FOREWORD

The American Institute of Steel Construction, founded in 1921, is the nonprofit technical standards developer and trade organization for the fabricated structural steel industry in the United States. AISC is headquartered in Chicago and has a long tradition of service to the steel construction industry providing timely and reliable information.

The continuing financial support and active participation of Members in the engineering, research and development activities of the Institute make possible the publishing of this *Steel Construction Manual.* Those Members include the following: Full Members engaged in the fabrication, production and sale of structural steel; Associate Members, who include erectors, detailers, service consultants, software developers and steel product manufacturers; Professional Members, who are structural or civil engineers and architects, including architectural and engineering educators; Affiliate Members, who include general contractors, building inspectors and code officials; and Student Members.

The Institute's objective is to make structural steel the material of choice, by being the leader in structural-steel-related technical and market-building activities, including specification and code development, research, education, technical assistance, quality certification, standardization and market development.

To accomplish this objective, the Institute publishes manuals, design guides and specifications. Best known and most widely used is the *Steel Construction Manual*, which holds a highly respected position in engineering literature. The Manual is based on the *Specification for Structural Steel Buildings* and the *Code of Standard Practice for Steel Buildings and Bridges*. Both standards are included in the Manual for easy reference.

The Institute also publishes technical information and timely articles in its *Engineering Journal*, Design Guide series, *Modern Steel Construction* magazine, and other design aids, research reports and journal articles. Nearly all of the information AISC publishes is available for download from the AISC web site at **www.aisc.org**.

PREFACE

This Manual is the 14th Edition of the AISC *Steel Construction Manual*, which was first published in 1927. It replaces the 13th Edition Manual originally published in 2005.

The following specifications, codes and standards are printed in Part 16 of this Manual:

- 2010 AISC *Specification for Structural Steel Buildings*
- 2009 RCSC *Specification for Structural Joints Using High-Strength Bolts*
- 2010 AISC *Code of Standard Practice for Steel Buildings and Bridges*

The following resources supplement the Manual and are available on the AISC web site at **www.aisc.org:**

- AISC *Design Examples*, which illustrate the application of tables and specification provisions that are included in this Manual.
- AISC *Shapes Database V14.0 and V14.0H.*
- Background and supporting literature (references) for the AISC *Steel Construction Manual.*

The following major changes and improvements have been made in this revision:

- All tabular information and discussions have been updated to comply with the 2010 *Specification for Structural Buildings* and the standards and other documents referenced therein.
- Shape information has been updated to ASTM A6-09 throughout the Manual, including a new HP shape series.
- Eccentrically loaded weld tables have been revised to indicate the strongest weld permitted by the three methods listed in Chapter J of the specification and supplemented to provide strengths for L-shaped welds loaded from either side.
- The procedure for the design of bracket plates in Part 15 has been revised.
- In Part 10, the procedure for the design of conventional single plate shear connections has been revised to accommodate the increased bolt shear strengths of the 2010 *Specification for Structural Steel Buildings.*
- In Part 10, for extended single plate shear connections, information is provided to determine if stiffening plates (stabilizers) are required.

In addition, many other improvements have been made throughout this Manual and the number of accompanying design examples has been expanded.

By the AISC Committee on Manuals and Textbooks,

The committee gratefully acknowledges the contributions made to this Manual by the AISC Committee on Specifications and the following individuals: Leigh C. Arber, Areti Carter, Janet T. Cummins, Amanuel Gebremeskel, Kurt Gustafson, Richard C. Kaehler, Daniel J. Kaufman, Rostislav Kucher, Brent L. Leu, Margaret A. Matthew, Frederick J. Palmer, Vijaykumar Patel, Elizabeth A. Rehwoldt, Thomas J. Schlafly, Zachary W. Stutts and Sriramulu Vinnakota.

SCOPE

The specification requirements and other design recommendations and considerations summarized in this Manual apply in general to the design and construction of steel buildings and other structures.

The design of seismic force resisting systems also must meet the requirements in the AISC *Seismic Provisions for Structural Steel Buildings*, except in the following cases for which use of the AISC *Seismic Provisions* is not required:

- Buildings and other structures in seismic design category (SDC) A
- Buildings and other structures in SDC B or C with $R = 3$ systems [steel systems not specifically detailed for seismic resistance per ASCE/SEI 7 Table 12.2-1 (ASCE, 2010)]
- Nonbuilding structures similar to buildings with $R = 1\frac{1}{2}$ braced-frame systems or $R = 1$ moment-frame systems; see ASCE/SEI 7 Table 15.4-1
- Nonbuilding structures not similar to buildings (see ASCE/SEI 7 Table 15.4-2), which are designed to meet the requirements in other standards entirely

Conversely, use of the AISC *Seismic Provisions* is required in the following cases:

- Buildings and other structures in SDC B or C when one of the exemptions for steel seismic force resisting systems above does not apply
- Buildings and other structures in SDC B or C that use composite seismic force resisting systems (those containing composite steel-and-concrete members and those composed of steel members in combination with reinforced concrete members)
- Buildings in SDC D, E or F
- Nonbuilding structures in SDC D, E or F when the exemption above does not apply

The AISC *Seismic Design Manual* provides guidance on the use of the AISC *Seismic Provisions*.

The Manual consists of seventeen parts addressing various topics related to steel building design and construction. Part 1 provides the dimensions and properties for structural products commonly used. For proper material specifications for these products, as well as general specification requirements and other design considerations, see Part 2. For the design of members, see Parts 3 through 6. For the design of connections, see Parts 7 through 15. For AISC Specifications and Codes, see Part 16. For other miscellaneous information, see Part 17.

PART 1

DIMENSIONS AND PROPERTIES

SCOPE

The dimensions and properties for structural products commonly used in steel building design and construction are given in this Part. Although the dimensions and properties tabulated in Part 1 reflect "commonly" used structural products, some of the shapes listed are not commonly produced or stocked. These shapes are usually only produced to order, and will likely be subject to mill production schedules and minimum order quantities. For availability of shapes, go to **www.aisc.org**. For torsional and flexural-torsional properties of rolled shapes see AISC Design Guide 9, *Torsional Analysis of Structural Steel Members* (Seaburg and Carter, 1997). For surface areas, box perimeters and areas, *W*/*D* ratios and *A*/*D* ratios, see AISC Design Guide 19, *Fire Resistance of Structural Steel Framing* (Ruddy et al., 2003).

STRUCTURAL PRODUCTS

W-, M-, S- and HP-Shapes

Four types of H-shaped (or I-shaped) members are covered in this Manual:

- W-shapes, which have essentially parallel inner and outer flange surfaces.
- M-shapes, which are H-shaped members that are not classified in ASTM A6 as W-, S- or HP-shapes. M-shapes may have a sloped inside flange face or other cross-section features that do not meet the criteria for W-, S- or HP-shapes.
- S-shapes (also known as American standard beams), which have a slope of approximately $16^2/_3$% (2 on 12) on the inner flange surfaces.
- HP-shapes (also known as bearing piles), which are similar to W-shapes except their webs and flanges are of equal thickness and the depth and flange width are nominally equal for a given designation.

These shapes are designated by the mark W, M, S or HP, nominal depth (in.) and nominal weight (lb/ft). For example, a W24×55 is a W-shape that is nominally 24 in. deep and weighs 55 lb/ft.

The following dimensional and property information is given in this Manual for the W-, M-, S- and HP-shapes covered in ASTM A6:

- Design dimensions, detailing dimensions, axial properties and flexural properties are given in Tables 1-1, 1-2, 1-3 and 1-4 for W-, M-, S- and HP-shapes, respectively.
- SI-equivalent designations are given in Table 17-1 for W-shapes and in Table 17-2 for M-, S- and HP-shapes.

Tabulated decimal values are appropriate for use in design calculations, whereas fractional values are appropriate for use in detailing. All decimal and fractional values are similar with one exception: Because of the variation in fillet sizes used in shape production, the decimal value, k_{des}, is conservatively presented based on the smallest fillet used in production, and the fractional value, k_{det}, is conservatively presented based on the largest fillet used in production. For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

When appropriate, this Manual presents tabulated values for the workable gage of a section. The term workable gage refers to the gage for fasteners in the flange that provides for entering and tightening clearances and edge distance and spacing requirements. When the listed value is footnoted, the actual size, combination, and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility. Other gages that provide for entering and tightening clearances and edge distance and spacing requirements can also be used.

Channels

Two types of channels are covered in this Manual:

- C-shapes (also known as American standard channels), which have a slope of approximately $16^2/_3$% (2 on 12) on the inner flange surfaces.
- MC-shapes (also known as miscellaneous channels), which have a slope other than $16^2/_3$% (2 on 12) on the inner flange surfaces.

These shapes are designated by the mark C or MC, nominal depth (in.) and nominal weight (lb/ft). For example, a C12×25 is a C-shape that is nominally 12 in. deep and weighs 25 lb/ft.

The following dimensional and property information is given in this Manual for the channels covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, flexural and torsional properties are given in Tables 1-5 and 1-6 for C- and MC-shapes, respectively.
- SI-equivalent designations are given in Table 17-3.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Angles

Angles (also known as L-shapes) have legs of equal thickness and either equal or unequal leg sizes. Angles are designated by the mark L, leg sizes (in.) and thickness (in.). For example, an L4×3×$^1/_2$ is an angle with one 4-in. leg, one 3-in. leg, and $^1/_2$-in. thickness.

The following dimensional and property information is given in this Manual for the angles covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, flexural and flexural-torsional properties are given in Table 1-7. The effects of leg-to-leg and toe fillet radii have been considered in the determination of these section properties. The S_z value that is given in Table 1-7 is based on the largest perpendicular distance measured from the z-axis to the center of the thickness at the tip of the angle toe(s) or heel. Additional properties of single angles are provided in the digital shapes database available at **www.aisc.org**. These properties are used for calculations involving z and w principal axes. For unequal leg angles, the database includes I, and values of S at the toe of the short leg, the heel, and the toe of the long leg, for the w and z principal axes. For equal leg angles, the database includes I, and values of S at the toe of the leg and the heel, for w and z principal axes.
- Workable gages on angle legs are tabulated in Table 1-7A.
- Compactness criteria for angles are tabulated in Table 1-7B.
- SI-equivalent designations are given in Table 17-4.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Structural Tees (WT-, MT- and ST-Shapes)

Three types of structural tees are covered in this Manual:

- WT-shapes, which are made from W-shapes
- MT-shapes, which are made from M-shapes
- ST-shapes, which are made from S-shapes

These shapes are designated by the mark WT, MT or ST, nominal depth (in.) and nominal weight (lb/ft). WT-, MT- and ST-shapes are split (sheared or thermal-cut) from W-, M- and S-shapes, respectively, and have half the nominal depth and weight of that shape. For example, a WT12×27.5 is a structural tee split from a W-shape (W24×55), is nominally 12 in. deep and weighs 27.5 lb/ft. Although off-center splitting or splitting on two lines can be obtained by special order, the resulting nonstandard shape is not covered in this Manual.

The following dimensional and property information is given in this Manual for the structural tees cut from the W-, M- and S-shapes covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, flexural and torsional properties are given in Tables 1-8, 1-9 and 1-10 for WT-, MT- and ST-shapes, respectively.
- SI-equivalent designations are given in Table 17-5 for WT-shapes and in Table 17-6 for MT- and ST-shapes.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Hollow Structural Sections (HSS)

Three types of HSS are covered in this Manual:

- Rectangular HSS, which have an essentially rectangular cross section, except for rounded corners, and uniform wall thickness, except at the weld seam(s)
- Square HSS, which have an essentially square cross section, except for rounded corners, and uniform wall thickness, except at the weld seam(s)
- Round HSS, which have an essentially round cross section and uniform wall thickness, except at the weld seam(s)

In each case, ASTM A500 covers only electric-resistance-welded (ERW) HSS with a maximum periphery of 64 in. The coverage of HSS in this Manual is similarly limited.

Rectangular HSS are designated by the mark HSS, overall outside dimensions (in.), and wall thickness (in.), with all dimensions expressed as fractional numbers. For example, an HSS10×10×1/2 is nominally 10 in. by 10 in. with a 1/2-in. wall thickness. Round HSS are designated by the term HSS, nominal outside diameter (in.), and wall thickness (in.) with both dimensions expressed to three decimal places. For example, an HSS10.000×0.500 is nominally 10 in. in diameter with a 1/2-in. nominal wall thickness.

Per AISC *Specification* Section B4.2, the wall thickness used in design, t_{des}, is taken as 0.93 times the nominal wall thickness, t_{nom}. The rationale for this requirement is explained in the corresponding *Specification* Commentary Section B4.2.

In calculating the tabulated b/t and h/t ratios, the outside corner radii are taken as $1.5t_{des}$ for rectangular and square HSS, per AISC *Specification* Section B4.1. In other tabulated design dimensions, the corner radii are taken as $2t_{des}$. In the tabulated workable flat dimensions of rectangular (and square) HSS, the outside corner radii are taken as $2.25t_{nom}$. The term workable flat refers to a reasonable flat width or depth of material for use in making connections to HSS. The workable flat dimension is provided as a reflection of current industry practice, although the tolerances of ASTM A500 allow a greater maximum corner radius of $3t_{nom}$.

The following dimensional and property information is given in this Manual for the HSS covered in ASTM A500, A501, A618 or A847:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural, weak-axis flexural, torsional, and flexural-torsional properties are given in Tables 1-11 and 1-12 for rectangular and square HSS, respectively.
- Design dimensions, detailing dimensions, and axial, flexural and torsional properties are given in Table 1-13 for round HSS.
- SI-equivalent designations are given in Tables 17-7, 17-8 and 17-9 for rectangular, square and round HSS, respectively.
- Compactness criteria of rectangular and square HSS are given in Table 1-12A.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Pipe

Pipes have an essentially round cross section and uniform thickness, except at the weld seam(s) for welded pipe.

Pipes up to and including NPS 12 are designated by the term Pipe, nominal diameter (in.) and weight class (Std., x-Strong, xx-Strong). NPS stands for nominal pipe size. For example, Pipe 5 Std. denotes a pipe with a 5-in. nominal diameter and a 0.258-in. wall thickness, which corresponds to the standard weight series. Pipes with wall thicknesses that do not correspond to the foregoing weight classes are designated by the term Pipe, outside diameter (in.), and wall thickness (in.) with both expressed to three decimal places. For example, Pipe 14.000×0.375 and Pipe 5.563×0.500 are proper designations.

Per AISC *Specification* Section B4.2, the wall thickness used in design, t_{des}, is taken as 0.93 times the nominal wall thickness, t_{nom}. The rationale for this requirement is explained in the corresponding *Specification* Commentary Section B4.2.

The following dimensional and property information is given in this Manual for the pipes covered in ASTM A53:

- Design dimensions, detailing dimensions, and axial, flexural and torsional properties are given in Table 1-14.
- SI-equivalent designations are given in Table 17-10.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Double Angles

Double angles (also known as 2L-shapes) are made with two angles that are interconnected through their back-to-back legs along the length of the member, either in contact for the full length or separated by spacers at the points of interconnection.

These shapes are designated by the mark 2L, the sizes and thickness of their legs (in.), and their orientation when the angle legs are not of equal size (LLBB or SLBB).[1] For example, a 2L4×3×1/2 LLBB has two angles with one 4-in. leg and one 3-in. leg and the 4-in. legs are back-to-back; a 2L4×3×1/2 SLBB is similar, except the 3-in. legs are back-to-back. In both cases, the legs are 1/2-in. thick.

The following dimensional and property information is given in this Manual for the double angles built-up from the angles covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural, weak-axis flexural, torsional, and flexural-torsional properties are given in Table 1-15 for equal-leg, LLBB and SLBB angles. In each case, angle separations of zero in., 3/8 in. and 3/4 in. are covered. The effects of leg-to-leg and toe fillet radii have been considered in the determination of these section properties. For workable gages on legs of angles, see Table 1-7A.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Double Channels

Double channels (also known as 2C- and 2MC-shapes) are made with two channels that are interconnected through their back-to-back webs along the length of the member, either in contact for the full length or separated by spacers at the points of interconnection.

These shapes are designated by the mark 2C or 2MC, nominal depth (in.), and nominal weight per channel (lb/ft). For example, a 2C12×25 is a double channel that consists of two channels that are each nominally 12 in. deep and each weigh 25 lb/ft.

The following dimensional and property information is given in this Manual for the double channels built-up from the channels covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural, and weak-axis flexural properties are given in Tables 1-16 and 1-17 for 2C- and 2MC-shapes, respectively. In each case, channel separations of zero, 3/8 in. and 3/4 in. are covered.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

W-Shapes and S-Shapes with Cap Channels

Common combined sections made with W- or S-shapes and channels (C- or MC-shapes) are tabulated in this Manual. In either case, the channel web is interconnected to the W-shape or S-shape top flange, respectively, with the flange toes down. The interconnection of the two elements must be designed for the horizontal shear, q, where

$$q = \frac{VQ}{I} \tag{1-1}$$

[1] LLBB stands for long legs back-to-back. SLBB stands for short legs back-to-back. Alternatively, the orientations LLV and SLV, which stand for long legs vertical and short legs vertical, respectively, can be used.

where

I = moment of inertia of the combined cross section, in.^{4}
Q = first moment of the channel area about the neutral axis of the combined cross section, in.^{3}
V = vertical shear, kips
q = horizontal shear, kips/in.

The effects of other forces, such as crane horizontal and lateral forces, may also require consideration, when applicable.

The following dimensional and property information is given in this Manual for combined sections built-up from the W-shapes, S-shapes and cap channels covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural, and weak-axis flexural properties of W-shapes with cap channels are given in Table 1-19.
- Design dimensions, detailing dimensions, and axial, strong-axis flexural, and weak-axis flexural properties of S-shapes with cap channels are given in Table 1-20.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Plate Products

Plate products may be ordered as sheet, strip or bar material. Sheet and strip are distinguished from structural bars and plates by their dimensional characteristics, as outlined in Table 2-3 and Table 2-5.

The historical classification system for structural bars and plates suggests that there is only a physical difference between them based upon size and production procedure. In raw form, flat stock has historically been classified as a bar if it is less than or equal to 8 in. wide and as a plate if it is greater than 8 in. wide. Bars are rolled between horizontal and vertical rolls and trimmed to length by shearing or thermal cutting on the ends only. Plates are generally produced using one of two methods:

1. Sheared plates are rolled between horizontal rolls and trimmed to width and length by shearing or thermal cutting on the edges and ends; or
2. Stripped plates are sheared or thermal cut from wider sheared plates.

There is very little, if any, structural difference between plates and bars. Consequently, the term plate is becoming a universally applied term today and a PL$^1/_2$ in.×4$^1/_2$ in.×1ft 3 in., for example, might be fabricated from plate or bar stock.

For structural plates, the preferred practice is to specify thickness in $^1/_{16}$-in. increments up to $^3/_8$-in. thickness, $^1/_8$-in. increments over $^3/_8$-in. to 1-in. thickness, and $^1/_4$-in. increments over 1-in. thickness. The current extreme width for sheared plates is 200 in. Because mill practice regarding plate widths vary, individual mills should be consulted to determine preferences.

For bars, the preferred practice is to specify width in $^1/_4$-in. increments, and thickness and diameter in $^1/_8$-in. increments.

Raised-Pattern Floor Plates

Weights of raised-pattern floor plates are given in Table 1-18. Raised-pattern floor plates are commonly available in widths up to 120 in. For larger plate widths, see literature available from floor plate producers.

Crane Rails

Although crane rails are not listed as structural steel in the AISC *Code of Standard Practice* Section 2.1, this information is provided because some fabricators may choose to provide crane rails. Crane rails are designated by unit weight in lb/yard. Dimensions and properties for the crane rails shown are given in Table 1-21. Crane rails can be either heat treated or end hardened to reduce wear. For additional information or for profiles and properties of crane rails not listed, manufacturer's catalogs should be consulted. For crane-rail connections, see Part 15.

Other Structural Products

The following other structural products are covered in this Manual as indicated:

- High-strength bolts, common bolts, washers, nuts and direct-tension-indicator washers are covered in Part 7.
- Welding filler metals and fluxes are covered in Part 8.
- Forged steel structural hardware items, such as clevises, turnbuckles, sleeve nuts, recessed-pin nuts, and cotter pins are covered in Part 15.
- Anchor rods and threaded rods are covered in Part 14.

STANDARD MILL PRACTICES

The production of structural products is subject to unavoidable variations relative to the theoretical dimensions and profiles, due to many factors, including roll wear, roll dressing practices and temperature effects. Such variations are limited by the dimensional and profile tolerances as summarized below.

Hot-Rolled Structural Shapes

Acceptable dimensional tolerances for hot-rolled structural shapes (W-, M-, S- and HP-shapes), channels (C- and MC-shapes), and angles are given in ASTM A6 Section 12 and summarized in Tables 1-22 through 1-26. Supplementary information, including permissible variations for sheet and strip and for other grades of steel, can also be found in literature from steel plate producers and the Association of Iron and Steel Technology.

Hollow Structural Sections

Acceptable dimensional tolerances for HSS are given in ASTM A500 Section 11, A501 Section 12, A618 Section 8, or A847 Section 10, as applicable, and summarized in Tables 1-27 and 1-28, for rectangular and round HSS, respectively. Supplementary information can also be found in literature from HSS producers and the Steel Tube Institute, such as *Recommended Methods to Check Dimensional Tolerances on Hollow Structural Sections (HSS) Made to ASTM A500.*

Pipe

Acceptable dimensional tolerances for pipes are given in ASTM A53 Section 10 and summarized in Table 1-28. Supplementary information can also be found in literature from pipe producers.

Plate Products

Acceptable dimensional tolerances for plate products are given in ASTM A6 Section 12 and summarized in Table 1-29. Note that plate thickness can be specified in inches or by weight per square foot, and separate tolerances apply to each method. No decimal edge thickness can be assured for plate specified by the latter method. Supplementary information, including permissible variations for sheet and strip and for other grades of steel, can also be found in literature from steel plate producers and the Association of Iron and Steel Technology.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.

[c] Shape is slender for compression with $F_y = 36$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 36$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[t] Shape has tapered flanges while other M-shapes have parallel flange surfaces.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(b)(i) with $F_y = 36$ ksi.
— Indicates flange is too narrow to establish a workable gage.

[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
— Indicates flange is too narrow to establish a workable gage.

[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
— Indicates flange is too narrow to establish a workable gage.

[c] Shape is slender for compression with F_y = 36 ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
— Indicates flange is too narrow to establish a workable gage.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with F_y = 50 ksi.
[f] Shape exceeds compact limit for flexure with F_y = 50 ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with F_y = 50 ksi.
[f] Shape exceeds compact limit for flexure with F_y = 50 ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.

[c] Shape is slender for compression with $F_y = 36$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 36$ ksi.
[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross section to ensure compatibility.
[t] This shape has tapered flanges while all other MT-shapes have parallel flange surfaces.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 36$ ksi.
— Indicates flange is too narrow to establish a workable gage.

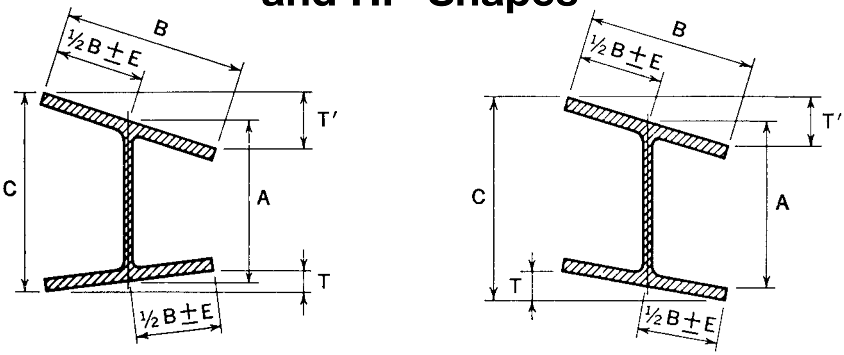
Table 1-22
ASTM A6 Tolerances for W-Shapes and HP-Shapes



Permissible Cross-Sectional Variations

Nominal Depth, in.	*A* Depth at Web Centerline, in.		*B* Flange Width, in.		*T* + *T′* Flanges Out of Square, Max. in.	*E*[a] Web Off Center, in.	*C*, Max. Depth at any Cross-Section over Theoretical Depth, in.
	Over	Under	Over	Under			
To 12, incl.	1/8	1/8	1/4	3/16	1/4	3/16	1/4
Over 12	1/8	1/8	1/4	3/16	5/16	3/16	1/4

Permissible Variations in Length

Nominal Depth[b], in.	Variations from Specified Length for Lengths Given, in.			
	30 ft and Under		Over 30 ft	
	Over	Under	Over	Under
Beams 24 in. and under	3/8	3/8	3/8 plus 1/16 for each additional 5 ft or fraction thereof	3/8
Beams over 24 in. All columns	1/2	1/2	1/2 plus 1/16 for each additional 5 ft or fraction thereof	1/2

Mill Straightness Tolerances[c]

Sizes	Length	Permissible Variation in Straightness, in.	
		Camber	Sweep
Flange width equal to or greater than 6 in.	All	$\frac{1}{8}\text{ in.} \times \frac{(\text{total length, ft})}{10}$	
Flange width less than 6 in.	All	$\frac{1}{8}\text{ in.} \times \frac{(\text{total length, ft})}{10}$	$\frac{1}{8}\text{ in.} \times \frac{(\text{total length, ft})}{5}$
Certain sections with a flange width approx. equal to depth & specified on order as columns[d]	45 ft and under	$\frac{1}{8}\text{ in.} \times \frac{(\text{total length, ft})}{10}$ with 3/8 in. max.	
	Over 45 ft	$\frac{3}{8}\text{ in.} + \left[\frac{1}{8}\text{ in.} \times \frac{(\text{total length, ft} - 45)}{10}\right]$	

Other Permissible Rolling Variations

Area and Weight	–2.5 to +3.0% from the theoretical cross-sectional area or the specified nominal weight[e]
Ends Out of Square	1/64 in., per in. of depth, or of flange width if it is greater than the depth

[a] Variation of 5/16 in. max. for sections over 426 lb/ft.
[b] For shapes specified in the order for use as bearing piles, the permitted variations are plus 5 in. and minus 0 in.
[c] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1-1.
[d] Applies only to W8×31and heavier, W10×49 and heavier, W12×65 and heavier, W14×90 and heavier, HP8×36, HP10×57, HP12×74 and heavier, and HP14×102 and heavier. If other sections are specified on the order as columns, the tolerance will be subject to negotiation with the manufacturer.
[e] For shapes with a nominal weight ≥ 100 lb/ft, the permitted variation is ±2.5% from the theoretical or specified amount.

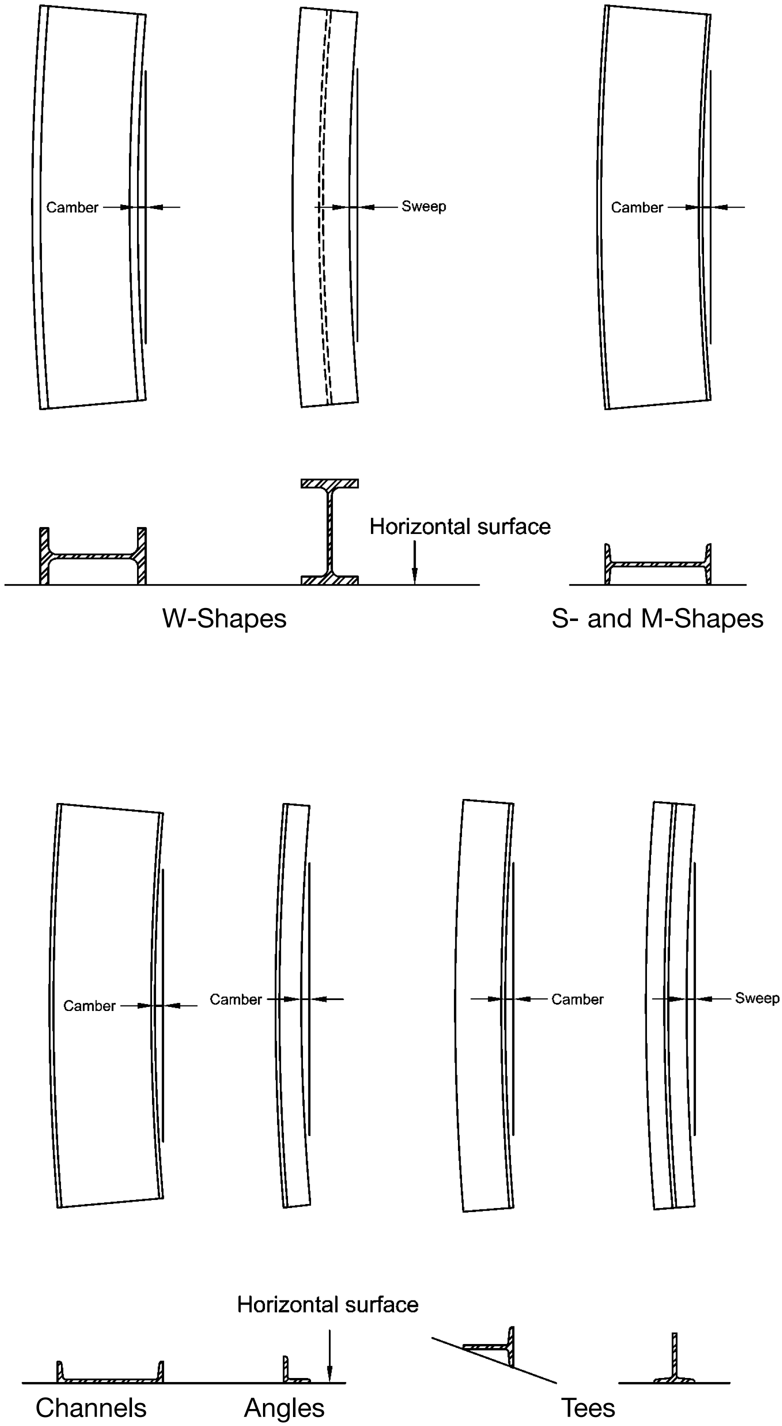


Fig. 1-1. Positions for measuring straightness.

Mill Straightness Tolerances[d]

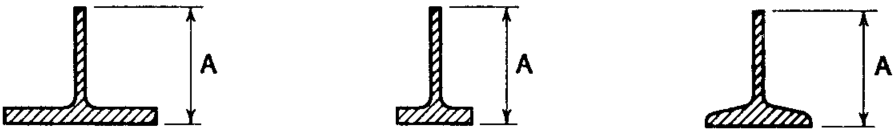
Camber	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$
Sweep	Due to the extreme variations in flexibility of these shapes, permitted variations for sweep are subject to negotiation between the manufacturer and purchaser for the individual sections involved.

Other Permissible Rolling Variations

Area and Weight	–2.5 to +3.0% from the theoretical cross-sectional area or the specified nominal weight[e]
Ends Out of Square	S-Shapes, M-Shapes and Channels 1/64 in., per in. of depth

— Indicates that there is no requirement.
[a] ***A*** is measured at center line of web for S-shapes and M-shapes and at back of web for channels.
[b] ***T*** + ***T′*** applies when flanges of channels are toed in or out.
[c] The permitted variation under the specified length is 0 in. for all lengths. There are no requirements for lengths over 65 ft.
[d] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1-1.
[e] For shapes with a nominal weight ≥ 100 lb/ft, the permitted variation is ±2.5% from the theoretical or specified amount.

Table 1-24
ASTM A6 Tolerances for WT-, MT- and ST-Shapes

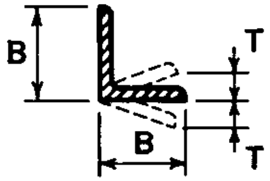


Permissible Variations in Depth	
Dimension A may be approximately one-half beam depth or any dimension resulting from off-center splitting or splitting on two lines, as specified in the order.	
Specified Depth, *A*, in.	**Variations in Depth *A*, Over and Under**
To 6, excl.	1/8
6 to 16, excl.	3/16
16 to 20, excl.	1/4
20 to 24, excl.	5/16
24 and over	3/8
The above variations in depths of tees include the permissible variations in depth for the beams before splitting	
Mill Straightness Tolerances[a]	
Camber and Sweep	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$
Other Permissible Rolling Variations	
Other permissible variations in cross section as well as permissible variations in length, area, weight, ends out-of-square, and sweep for WTs will correspond to those of the beam before splitting.	

— Indicates that there is no requirement.

[a] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1-1. For tolerance on induced camber and sweep, see AISC *Code of Standard Practice* Section 6.4.4.

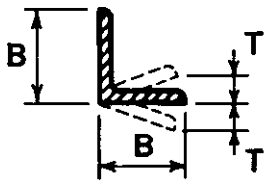
Table 1-25
ASTM A6 Tolerances for Angles, 3 in. and Larger



Permissible Cross-Sectional Variations				
Shape	**Nominal Leg Size[a], in.**	***B* Leg Size, in.**		***T* Out of Square per in. of *B*, in.**
		Over	**Under**	
Angles	3 to 4, incl.	1/8	3/32	3/128[b]
	Over 4 to 6, incl.	1/8	1/8	
	Over 6	3/16	1/8	
Permissible Variations in Length				
Variations Over Specified Length for Lengths Given[c], in.				
5 to 10 ft, excl.	**10 to 20 ft, excl.**	**20 to 30 ft, incl.**	**Over 30 to 40 ft, incl.**	**Over 40 to 65 ft, incl.**
1	1 1/2	1 3/4	2 1/4	2 3/4
Mill Straightness Tolerances[d]				
Camber	$\frac{1}{8}$ in. $\times \frac{\text{(total length, ft)}}{5}$, applied to either leg			
Sweep	Due to the extreme variations in flexibility of these shapes, permitted variations for sweep are subject to negotiation between the manufacturer and purchaser for the individual sections involved.			
Other Permissible Rolling Variations				
Area and Weight	–2.5 to +3.0% from the theoretical cross-sectional area or the specified nominal weight			
Ends Out of Square	3/128 in. per in. of leg length, or 1 1/2°. Variations based on the longer leg of unequal angle.			

[a] For unequal leg angles, longer leg determines classification.
[b] 3/128 in. per in. = 1 1/2°
[c] The permitted variation under the specified length is 0 in. for all lengths. There are no requirements for lengths over 65 ft.
[d] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1-1.

Table 1-26
ASTM A6 Tolerances for Angles, < 3 in.



Permissible Cross-Sectional Variations					
Specified Leg Size[a], in.	Variations in Thickness for Thicknesses Given, Over and Under, in.			*B* Leg Size, Over and Under, in.	*T* Out of Square per Inch of *B*, in.
	$^{3}/_{16}$ and Under	Over $^{3}/_{16}$ to $^{3}/_{8}$ incl.	Over $^{3}/_{8}$		
1 and Under	0.008	0.010	—	$^{1}/_{32}$	$^{3}/_{128}$[b]
Over 1 to 2, incl.	0.010	0.010	0.012	$^{3}/_{64}$	
Over 2 to 3, excl.	0.012	0.015	0.015	$^{1}/_{16}$	

Permissible Variations in Length					
Section	Variations Over Specified Length for Lengths Given[c], in.				
	5 to 10 ft, excl.	10 to 20 ft, excl.	20 to 30 ft, incl.	Over 30 to 40 ft, incl.	40 to 65 ft, incl.
All bar-size angles	$^{5}/_{8}$	1	$1^{1}/_{2}$	2	$2^{1}/_{2}$

Mill Straightness Tolerances[d]	
Camber	$^{1}/_{4}$ in. in any 5 ft, or $^{1}/_{4}$ in. $\times \frac{\text{(total length, ft)}}{5}$, applied to either leg
Sweep	Due to the extreme variations in flexibility of these shapes, permitted variations for sweep are subject to negotiation between the manufacturer and purchaser for the individual sections involved.

Other Permissible Rolling Variations	
Ends Out of Square	$^{3}/_{128}$ in. per in. of leg length, or $1^{1}/_{2}°$. Variations based on the longer leg of unequal angle.

— Indicates that there is no requirement.
[a] For unequal angles, longer leg determines classification.
[b] $^{3}/_{128}$ in. per in. = $1^{1}/_{2}°$
[c] The permitted variation under the specified length is 0 in. for all lengths. There are no requirements for lengths over 65 ft.
[d] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1-1.

6 to 8, excl.	7/16	1/2	1/2	5/8	11/16	3/4	7/8	7/8

Notes:
1. The longer dimension specified is considered the length, and permissible variations in flatness along the length shall not exceed the tabular amount for the specified width for plates up to 12 ft in length, or in any 12 ft for longer plates.
2. The flatness variations across the width shall not exceed the tabular amount for the specified width.
3. When the longer dimension is under 36 in., the permissible variation shall not exceed 1/4 in. When the longer dimension is from 36 to 72 in., inclusive, the permissible variation should not exceed 75% of the tabular amount for the specified width, but in no case less than 1/4 in.
4. These variations apply to plates which have a specified minimum tensile strength of not more than 60 ksi or comparable chemistry or hardness. The limits in the table are increased 50% for plates specified to a higher minimum tensile strength or comparable chemistry or hardness.
5. For plates 8 in. and over in thickness or 120 in. and over in width, see ASTM A6 Table 13.
6. Plates must be in a horizontal position on a flat surface when flatness is measured.

Permissible Variations in Camber[a] for Carbon Steel Sheared and Gas Cut Rectangular Plates

$$\text{Maximum permissible camber, in. (all thicknesses)} = \tfrac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$$

Permissible Variations in in Camber[a] for High-Strength Low-Alloy and Alloy Steel Sheared, Special-Cut, or Gas-Cut Rectangular Plates

Specified Dimension, in.		Permitted Camber, in.
Thickness	Width	
To 2, incl.	All	$\tfrac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$
Over 2 to 15, incl.	To 30, incl.	$\tfrac{3}{16}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$
	Over 30 to 60, incl.	$\tfrac{1}{4}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$

[a] Camber as it relates to plates is the horizontal edge curvature in the length, measured over the entire length of the plate in the flat position.

PART 2

GENERAL DESIGN CONSIDERATIONS

SCOPE

The specification requirements and other design considerations summarized in this Part apply in general to the design and construction of steel buildings. The specifications, codes and standards listed below are referenced throughout this manual.

APPLICABLE SPECIFICATIONS, CODES AND STANDARDS

Specifications, Codes and Standards for Structural Steel Buildings

Subject to the requirements in the applicable building code and the contract documents, the design, fabrication and erection of structural steel buildings is governed as indicated in the AISC *Specification* Sections A1 and B2 as follows:

1. ASCE/SEI 7: *Minimum Design Loads for Buildings and Other Structures,* ASCE/SEI 7-10 (ASCE, 2010). Available from the American Society of Civil Engineers, ASCE/SEI 7 provides the general requirements for loads, load factors and load combinations.
2. AISC *Specification*: The 2010 AISC *Specification for Structural Steel Buildings* (ANSI/AISC 360-10), included in Part 16 of this Manual and available at **www.aisc.org**, provides the general requirements for design and construction (AISC, 2010a).
3. AISC *Code of Standard Practice*: The 2010 AISC *Code of Standard Practice for Steel Buildings and Bridges* (AISC, 2010c) included in Part 16 of this manual and available at **www.aisc.org**, provides the standard of custom and usage for the fabrication and erection of structural steel.

Other referenced standards include:

1. RCSC *Specification*: The 2009 RCSC *Specification for Structural Joints Using High-Strength Bolts*, reprinted in Part 16 of this Manual with the permission of the Research Council on Structural Connections and available at **www.boltcouncil.org**, provides the additional requirements specific to bolted joints with high-strength bolts (RCSC, 2009).
2. AWS D1.1: *Structural Welding Code – Steel*, AWS D1.1:2010 (AWS, 2010). Available from the American Welding Society, AWS D1.1 provides additional requirements specific to welded joints. Requirements for the proper specification of welds can be found in AWS A2.4: *Standard Symbols for Welding, Brazing, and Nondestructive Examination* (AWS, 2007).
3. ACI 318: *Building Code Requirements for Structural Concrete and Commentary* (ACI, 2008). Available from the American Concrete Institute, ACI 318 provides additional requirements for reinforced concrete, including composite design and the design of steel-to-concrete anchorage.

Various other specifications and standards from ASME, ASTM and ACI are also referenced in AISC *Specification* Section A2.

Additional Requirements for Seismic Applications

The 2010 AISC *Seismic Provisions for Structural Steel Buildings* (AISC, 2010b) apply as indicated in Section A1.1 of the 2010 AISC *Specification* and in the Scope provided at the front of this Manual. The AISC *Seismic Provisions* are available at **www.aisc.org**.

Other AISC Reference Documents

The following other AISC publications may be of use in the design and construction of structural steel buildings:

1. AISC *Detailing for Steel Construction*, Third Edition, covers the standard practices and recommendations for steel detailing, including preparation of shop and erection drawings (AISC, 2009).
2. The AISC *Seismic Design Manual* (AISC, 2006) provides guidance on steel design in seismic applications, in accordance with the 2005 AISC *Seismic Provisions for Structural Steel Buildings*.
3. The AISC *Design Examples* is a web-based companion to this Manual and can be found at **www.aisc.org** (AISC, 2011). It includes design examples outlining the application of design aids and AISC *Specification* provisions developed in coordination with this Manual.

Additionally, the following AISC Design Guides are available at **www.aisc.org** for in-depth coverage of specific topics in steel design:

1. *Base Plate and Anchor Rod Design*, Design Guide 1 (Fisher and Kloiber, 2006)
2. *Steel and Composite Beams with Web Openings*, Design Guide 2 (Darwin, 1990)
3. *Serviceability Design Considerations for Steel Buildings*, Design Guide 3 (West et al., 2003)
4. *Extended End-Plate Moment Connections—Seismic and Wind Applications*, Design Guide 4 (Murray and Sumner, 2003)
5. *Low- and Medium-Rise Steel Buildings*, Design Guide 5 (Allison, 1991).
6. *Load and Resistance Factor Design of W-Shapes Encased in Concrete*, Design Guide 6 (Griffis, 1992)
7. *Industrial Buildings—Roofs to Anchor Rods*, Design Guide 7 (Fisher, 2004)
8. *Partially Restrained Composite Connections*, Design Guide 8 (Leon et al., 1996)
9. *Torsional Analysis of Structural Steel Members*, Design Guide 9 (Seaburg and Carter, 1997)
10. *Erection Bracing of Low-Rise Structural Steel Buildings*, Design Guide 10 (Fisher and West, 1997)
11. *Floor Vibrations Due to Human Activity*, Design Guide 11 (Murray et al., 1997)
12. *Modification of Existing Welded Steel Moment Frame Connections for Seismic Resistance*, Design Guide 12 (Gross et al., 1999)
13. *Stiffening of Wide-Flange Columns at Moment Connections: Wind and Seismic Applications*, Design Guide 13 (Carter, 1999)
14. *Staggered Truss Framing Systems*, Design Guide 14 (Wexler and Lin, 2002)
15. *AISC Rehabilitation and Retrofit Guide—A Reference for Historic Shapes and Specifications*, Design Guide 15 (Brockenbrough, 2002)
16. *Flush and Extended Multiple-Row Moment End-Plate Connections*, Design Guide 16 (Murray and Shoemaker, 2002)
17. *High Strength Bolts—A Primer for Structural Engineers,* Design Guide 17 (Kulak, 2002)
18. *Steel-Framed Open-Deck Parking Structures,* Design Guide 18 (Churches et al. 2003)
19. *Fire Resistance of Structural Steel Framing,* Design Guide 19 (Ruddy et al., 2003)
20. *Steel Plate Shear Walls,* Design Guide 20 (Sabelli and Bruneau, 2006)

21. *Welded Connections—A Primer for Engineers,* Design Guide 21 (Miller, 2006)
22. *Façade Attachments to Steel-Framed Buildings,* Design Guide 22 (Parker, 2008)
23. *Constructability of Structural Steel Buildings,* Design Guide 23 (Ruby, 2008)
24. *Hollow Structural Section Connections*, Design Guide 24 (Packer et al., 2010)
25. *Web-Tapered Frame Design*, Design Guide 25 (Kaehler et al., 2010)

OSHA REQUIREMENTS

OSHA *Safety and Health Standards for the Construction Industry*, *29 CFR 1926 Part R Safety Standards for Steel Erection* (OSHA, 2001) must be addressed in the design, detailing, fabrication and erection of steel structures. These regulations became effective on July 18, 2001.

Following is a brief summary of selected provisions and related recommendations. The full text of the regulations should be consulted and can be found at **www.osha.gov**. See also Barger and West (2001) for further information.

Columns and Column Base Plates

1. All column base plates must be designed and fabricated with a minimum of four anchor rods.
2. Posts (which weigh less than 300 lb) are distinguished from columns and excluded from the four-anchor-rod requirement.
3. Columns, column base plates, and their foundations must be designed to resist a minimum eccentric gravity load of 300 lb located 18 in. from the extreme outer face of the column in each direction at the top of the column shaft.
4. Column splices must be designed to meet the same load-resisting characteristics as columns.
5. Double connections through column webs or at beams that frame over the tops of columns must be designed to have at least one installed bolt remain in place to support the first beam while the second beam is being erected. Alternatively, the fabricator must supply a seat or equivalent device with a means of positive attachment to support the first beam while the second beam is being erected.

These features should be addressed in the construction documents. Items 1 through 4 are prescriptive, and alternative means such as guying are time consuming and costly. There are several methods to address the condition in item 5, as shown in Chapter 2 of AISC *Detailing for Steel Construction*.

Safety Cables

1. On multi-story structures, perimeter safety cables (two lines) are required at final interior and exterior perimeters of floors as soon as the deck is installed.
2. Perimeter columns must extend 48 in. above the finished floor (unless constructability does not allow) to allow the installation of perimeter safety cables.
3. The regulations prohibit field welding of attachments for installation of perimeter safety cables once the column has been erected.
4. Provision of some method of attaching the perimeter cable is required, but responsibility is not assigned either to the fabricator or to the erector. While this will be subject

to normal business arrangements between the fabricator and the erector, holes for these cables are often punched or drilled in columns by the fabricator.

The primary consideration in the design of the frame based on these rules is that the position of the column splice is set with respect to the floor.

Beams and Bracing

1. Solid-web members (beams) must be connected with a minimum of two bolts or their equivalent before the crane load line is released.
2. Bracing members must be connected with a minimum of one bolt or its equivalent before the crane load line is released.

The OSHA regulations allow an alternative to these minimums, if an "equivalent as specified by the project structural engineer of record" is provided. If the project requirements do not permit the use of bolts as described in items 1 and 2, then the "equivalent" means should be provided in the construction documents. It is recommended that the "equivalent" means should utilize bolts and removable connection material, and should provide requirements for the final condition of the connection. Solutions that employ shoring or the need to hold the member on the crane should be avoided.

Cantilevers

1. The erector is responsible for the stability of cantilevers and their temporary supports until the final cantilever connection is completed. OSHA 1926.756(a)(2) requires that a competent person shall determine if more than two bolts are necessary to ensure the stability of cantilevered members. Cantilever connections must be evaluated for the loads imposed on them during erection and consideration must be made for the intermediate states of completion, including the connection of the backspan member opposing the cantilever.

Certain cantilever connections can facilitate the erector's work in this regard, such as shop attaching short cantilevers, one piece cantilever/backspan beams carried through or over the column at the cantilever and field bolted flange plates or end plate connections to the supporting member. To the extent allowed by the contract documents, the selection of details is up to the fabricator, subject to normal business relations between the fabricator and the erector.

Joists

1. Unless panelized, all joists 40 ft long and longer and their bearing members must have holes to allow for initial connections by bolting.
2. Establishment of bridging terminus points for joists is mandated according to OSHA and manufacturer guidelines.
3. A vertical stabilizer plate to receive the joist bottom chord must be provided at columns. Minimum sizes are given and the stabilizer plate must have a hole for the attachment of guying or plumbing cables.

These features should be addressed in the construction documents and shop drawings.

Walking/Working Surfaces

1. Framed metal deck openings must have structural members configured with projecting elements turned down to allow continuous decking, except where not allowed by design constraints or constructability. The openings in the metal deck are not to be cut until the hole is needed.
2. Steel headed stud anchors, threaded studs, reinforcing bars and deformed anchors that will project vertically from or horizontally across the top flange of the member are not to be attached to the top flanges of beams, joists or beam attachments until after the metal decking or other walking/working surface has been installed.

Framing at openings with down turned elements and shop versus field attachment of anchors should be addressed in the construction documents and the shop drawings.

Controlling Contractor

1. The controlling contractor must provide adequate site access and adequate storage.
2. The controlling contractor must notify the erector of repairs or modifications to anchor rods in writing. Such modifications and repairs must be approved by the owner's designated representative for design.
3. The controlling contractor must give notice that the supporting foundations have achieved sufficient strength to allow safe steel erection.
4. The controlling contractor must either provide overhead protection or prohibit other trades from working under steel erection activities.

These provisions establish relationships among the erector, controlling contractor and owner's representative for design that all parties need to be aware of.

USING THE 2010 AISC SPECIFICATION

The 2010 AISC *Specification for Structural Steel Buildings* (ANSI/AISC 360-10) continues the format established in the 2005 edition of the *Specification* (AISC, 2005), ANSI/AISC 360-05, which unified the design provisions formerly presented in the 1989 *Specification for Structural Steel Buildings—Allowable Stress Design and Plastic Design* and the 1999 *Load and Resistance Factor Design Specification for Structural Steel Buildings*. The 2005 *Specification for Structural Steel Buildings* also integrated into a single document the information previously provided in the 1993 *Load and Resistance Factor Design Specification for Single-Angle Members* and the 1997 *Specification for the Design of Steel Hollow Structural Sections*. The 2010 AISC *Specification*, in combination with the 2010 *Seismic Provisions for Structural Steel Buildings* (ANSI/AISC 341-10), brings together all of the provisions needed for the design of structural steel in buildings and other structures.

The 2010 AISC *Specification* continues to present two approaches for the design of structural steel members and connections. Chapter B establishes the general requirements for analysis and design. It states that "designs shall be made according to the provisions for Load and Resistance Factor Design (LRFD) or to the provisions for Allowable Strength Design (ASD)." These two approaches are equally valid for any structure for which the *Specification* is applicable. There is no preference stated or implied in the provisions.

The required strength of structural members and connections may be determined by elastic, inelastic or plastic analysis for the load combinations associated with LRFD and by elastic analysis for load combinations associated with ASD and as stipulated by the applicable building code. In all cases, the available strength must exceed the required strength. The AISC *Specification* gives provisions for determining the available strength as summarized below.

Load and Resistance Factor Design (LRFD)

The load combinations appropriate for LRFD are given in the applicable building code or, in its absence, ASCE/SEI 7 Section 2.3. For LRFD, the available strength is referred to as the design strength. All of the LRFD provisions are structured so that the design strength must equal or exceed the required strength. This is presented in AISC *Specification* Section B3.3 as

$$R_u \le \phi R_n \tag{2–1}$$

In this equation, R_u is the required strength determined by analysis for the LRFD load combinations, R_n is the nominal strength determined according to the AISC *Specification* provisions, and ϕ is the resistance factor given by the AISC *Specification* for a particular limit state. Throughout this Manual, tabulated values of ϕR_n, the design strength, are given for LRFD. These values are tabulated as blue numbers in columns with the heading LRFD.

If there is a desire to use the LRFD provisions in the form of stresses, the strength provisions can be transformed into stress provisions by factoring out the appropriate section property. In many cases, the provisions are already given directly in terms of stress.

Allowable Strength Design (ASD)

Allowable strength design is similar to what is known as allowable stress design in that they are both carried out at the same load level. Thus, the same load combinations are used. The difference is that for strength design, the primary provisions are given in terms of forces or moments rather than stresses. In every situation, these strength provisions can be transformed into stress provisions by factoring out the appropriate section property. In many cases, the provisions are already given directly in terms of stress.

The load combinations appropriate for ASD are given by the applicable building code or, in its absence, ASCE/SEI 7 Section 2.4. For ASD, the available strength is referred to as the allowable strength. All of the ASD provisions are structured so that the allowable strength must equal or exceed the required strength. This is presented in AISC *Specification* Section B3.4 as

$$R_a \le \frac{R_n}{\Omega} \tag{2–2}$$

In this equation, R_a is the required strength determined by analysis for the ASD load combinations, R_n is the nominal strength determined according to the AISC *Specification* provisions and Ω is the safety factor given by the *Specification* for a particular limit state. Throughout this Manual, tabulated values of R_n/Ω, the allowable strength, are given for ASD. These values are tabulated as black numbers on a green background in columns with the heading ASD.

DESIGN FUNDAMENTALS

It is commonly believed that ASD is an elastic design method based entirely on a stress format without limit states and LRFD is an inelastic design method based entirely on a strength format with limit states. Traditional ASD was based on limit-states principles too, but without the use of the term. Additionally, either method can be formulated in a stress or strength basis, and both take advantage of inelastic behavior. The AISC *Specification* highlights how similar LRFD and ASD are in its formulation, with identical provisions throughout for LRFD and ASD.

Design according to the AISC *Specification*, whether it is according to LRFD or ASD, is based on limit states design principles, which define the boundaries of structural usefulness. Strength limit states relate to load carrying capability and safety. Serviceability limit states relate to performance under normal service conditions. Structures must be proportioned so that no applicable strength or serviceability limit state is exceeded.

Normally, several limit states will apply in the determination of the nominal strength of a structural member or connection. The controlling limit state is normally the one that results in the least available strength. As an example, the controlling limit state for bending of a simple beam may be yielding, local buckling, or lateral-torsional buckling for strength and deflection, or vibration for serviceability. The tabulated values may either reflect a single limit state or a combination of several limit states. This will be clearly stated in the introduction to the particular tables.

Loads, Load Factors and Load Combinations

Based on AISC *Specification* Sections B3.3 and B3.4, the required strength (either P_u, M_u, V_u, etc. for LRFD or P_a, M_a, V_a, etc. for ASD) is determined for the appropriate load magnitudes, load factors and load combinations given in the applicable building code. These are usually based on ASCE/SEI 7, which may be used when there is no applicable building code. The common loads found in building structures are:

D = dead load
L = live load due to occupancy
L_r = roof live load
S = snow load
R = nominal load due to initial rainwater or ice exclusive of the ponding contribution
W = wind load
E = earthquake load

Load and Resistance Factor Design

For LRFD, the required strength is determined from the following factored combinations,[1] which are based on ASCE/SEI 7 Section 2.3:

1. $1.4D$ (2-3a)
2. $1.2D + 1.6L + 0.5(L_r \text{ or } S \text{ or } R)$ (2-3b)
3. $1.2D + 1.6(L_r \text{ or } S \text{ or } R) + (0.5L \text{ or } 0.5W)$ (2-3c)
4. $1.2D + 1.0W + 0.5L + 0.5(L_r \text{ or } S \text{ or } R)$ (2-3d)

[1] Exception: Per ASCE/SEI 7, the load factor on L in combinations 3, 4 and 5 shall equal 1.0 for garages, areas occupied as places of public assembly, and all areas where the live load is greater than 100 psf.

5. $1.2D + 1.0E + 0.5L + 0.2S$ (2-3e)
6. $0.9D + 1.0W$ (2-3f)
7. $0.9D + 1.0E$ (2-3g)

The load combinations for LRFD recognize that, when several transient loads act in combination, only one assumes its maximum lifetime value,[2] while the other(s) are at their "arbitrary-point-in-time" (APT) values. Each combination models the total design loading condition when a different load is at its maximum. Thus, the maximum-lifetime load effect is amplified by an amount that is proportional to its relative variability and the APT load effect(s) are factored to their mean value(s). With this approach, the margin of safety varies with the load combination yielding a more uniform reliability than would be expected when nominal loads are combined directly.

Dead load, D, is present in each load combination with a load factor of 1.2, except in load combination 1, where it is the dominant (only) load effect, and load combinations 6 and 7, where it is reduced for calculation of the overturning or uplift effect. The 1.2 load factor accounts for the statistical variability of the dead load. The designer must independently account for other contributions to dead load, such as the weight of additional concrete, if any, added to adjust for concrete ponding effects (Ruddy, 1986) or differing framing elevations.

Allowable Strength Design

For ASD, the required strength is determined from the following combinations, which are also based on ASCE/SEI 7 Section 2.4:

1. D (2-4a)
2. $D + L$ (2-4b)
3. $D + (L_r \text{ or } S \text{ or } R)$ (2-4c)
4. $D + 0.75L + 0.75(L_r \text{ or } S \text{ or } R)$ (2-4d)
5. $D + (0.6W \text{ or } 0.7E)$ (2-4e)

6a. $D + 0.75L + 0.75(0.6W) + 0.75(L_r \text{ or } S \text{ or } R)$ (2-4f)

6b. $D + 0.75L + 0.75(0.7E) + 0.75S$ (2-4g)

7. $0.6D + 0.6W$ (2-4h)
8. $0.6D + 0.7E$ (2-4i)

The load combinations for ASD combine the code-specified nominal loads directly with no factors for those cases where loads with minimal variation with time are combined, cases 1, 2 and 3. For those cases where multiple time-variable loads are included, a 0.75 reduction factor is applied to the time-variable loads only. Since all of the safety in an ASD design comes through the introduction of the safety factor on the resistance side of the equation, each load case uses the same safety factor for a given limit state.

In ASD, when considering members subjected to gravity loading only, it is clear that the controlling load combination is the one that adds the larger live load to the dead load. Thus, for a floor that does not carry roof load, the controlling combination will be $D + L$ while for a roof the controlling combination will be $D + (L_r$ or S or $R)$. For gravity columns, after live load reductions have been accounted for, the floor and roof live loads may be reduced to 0.75 of their nominal values. A similar reduction is permitted for live loads in combination with lateral loads.

[2] Usually based upon a 50-year recurrence, except for seismic loads.

Superposition of Loads in Load Combinations

Whether the loads themselves or the effects of those loads are used in these combinations, LRFD or ASD, the results are the same, provided the principle of superposition is valid. This is true when deflections are small and the stress-strain behavior is nominally elastic. However, when second-order effects are significant or the behavior is inelastic, superposition is not valid and the loads, rather than the load effects, should be used in these combinations.

Nominal Strengths, Resistance Factors, Safety Factors and Available Strengths

The AISC *Specification* requires that the available strength must be greater than or equal to the required strength for any element. The available strength is a function of the nominal strength given by the *Specification* and the corresponding resistance factor or safety factor. As discussed earlier, the required strength can be determined either with LRFD or ASD load combinations.

The available strength for LRFD is the design strength, which is calculated as the product of the resistance factor ϕ and the nominal strength (ϕP_n, ϕM_n, ϕV_n, etc.) The available strength for ASD is the allowable strength, which is calculated as the quotient of the nominal strength and the corresponding safety factor Ω (P_n/Ω, M_n/Ω, V_n/Ω, etc.).

In LRFD, the margin of safety for the loads is contained in the load factors, and resistance factors, ϕ, to account for unavoidable variations in materials, design equations, fabrication and erection. In ASD, a single margin of safety for all of these effects is contained in the safety factor, Ω.

The resistance factors, ϕ, and safety factors, Ω, in the AISC *Specification* are based upon research, as discussed in the AISC *Specification* Commentary to Chapter B, and the experience and judgment of the AISC Committee on Specifications. In general, ϕ is less than unity and Ω is greater than unity. The higher the variability in the test data for a given nominal strength, the lower its ϕ factor and the higher its Ω factor will be. Some examples of ϕ and Ω factors for steel members are as follows:

$\phi = 0.90$ for limit states involving yielding
$\phi = 0.75$ for limit states involving rupture

$\Omega = 1.67$ for limit states involving yielding
$\Omega = 2.00$ for limit states involving rupture

The general relationship between the safety factor, Ω, and the resistance factor, ϕ, is

$$\Omega = \frac{1.5}{\phi} \tag{2–5}$$

Serviceability

Serviceability requirements of the AISC *Specification* are found in Section B3.9 and Chapter L. The serviceability limit states should be selected appropriately for the specific application as discussed in the *Specification* Commentary to Chapter L. Serviceability limit states and the appropriate load combinations for checking their conformance to serviceability requirements can be found in ASCE/SEI 7 Appendix C and its Commentary. It should be noted that the load combinations in ASCE/SEI 7 Section 2.3 for LRFD and Section 2.4 for ASD are both for strength design, and are not necessarily appropriate for consideration of serviceability.

Guidance is also available in the Commentary to the AISC *Specification*, both in general and for specific criteria, including camber, deflection, drift, vibrations, wind-induced motion, expansion and contraction, and connection slip. Additionally, the applicable building code may provide some further guidance or establish requirements. See also the serviceability discussions in Parts 3 through 6, AISC Design Guide 3, *Serviceability Design Considerations for Steel Buildings* (West et al., 2003) and AISC Design Guide 11, *Floor Vibrations Due to Human Activity* (Murray et al., 1997).

Structural Integrity

Structural integrity as introduced into building codes and the 2010 AISC *Specification* Section B3.2, is a set of prescriptive requirements for connections that, when met, are intended to provide an unknown, but satisfactory, level of performance of the finished structure. The term structural integrity has often been used interchangeably with progressive collapse, but these two concepts have widely varying interpretations that can influence design in a variety of ways. The term progressive collapse does not appear in the *International Building Code* (ICC, 2009) or in the 2010 AISC *Specification*. Progressive collapse requirements generally are intended to prevent the collapse of a structure beyond a localized area of the structure where a structural element has been compromised. Progressive collapse requirements are often mandated for government facilities, or by owners for structures which have a high probability of being subject to terrorist attack.

Structural integrity has always been one of the goals for the structural engineer in engineering design, and for the committees writing design standards. However, it has only been since the collapse of the buildings at the World Trade Center that requirements with the stated purpose of addressing structural integrity have appeared in U.S. building codes. The first building code to incorporate specific structural integrity requirements was the 2008 New York City Building Code which was quickly followed by requirements in the 2009 *International Building Code*. Although the requirements of these two building codes are both prescriptive in nature, there are some differences in requirements and their application. The AISC *Specification* Section B3.2 addresses the requirements of the 2009 *International Building Code*.

The 2009 *International Building Code* stipulates minimum integrity provisions for buildings classified as high-rise and assigned to Occupancy Categories III or IV. High-rise buildings are defined as those having an occupied floor greater than 75 ft above fire department vehicle access. The structural integrity requirements state that column splices must resist a minimum tension force and beam end connections must resist a minimum axial tension force. The nominal axial tension strength of the beam end connection must equal or exceed either the required vertical shear strength for ASD or $^2/_3$ the required vertical shear strength for LRFD. These required strengths can be reduced by 50% if the beam supports a composite deck with the prescribed steel anchors (Geschwindner and Gustafson, 2010).

The *International Building Code* structural integrity requirements for the axial tension capacity of the beam end connections use a nominal strength basis reflecting the intent of the code to avoid brittle rupture failures of the connection components, rather than limiting deformations or yielding of those components. Section B3.2 of the 2010 AISC *Specification* is based on this difference in limit state requirements for resistance to the prescriptive structural integrity loads, as compared to those limit states required when designing for traditional load combinations.

Progressive Collapse

Progressive collapse is defined in ASCE/SEI 7-10 (ASCE, 2010) as "the spread of an initial local failure from element to element resulting, eventually, in the collapse of an entire structure or a disproportionately large part of it."

Progressive collapse requirements often involve assessment of the structure's ability to accommodate loss of a member that has been compromised through redistribution of forces throughout the remaining structure. Design for progressive collapse poses a particularly challenging problem since it is difficult to identify the load cases to be examined or the members that may be compromised. Two main sources of requirements for evaluation of structures for progressive collapse are the Department of Defense and the General Services Administration. For facilities covered by the Department of Defense, all new and existing buildings of three stories or more must be designed to avoid progressive collapse. The specific requirements are published in United Facilities Criteria 4-023-03, "Design of Buildings to Resist Progressive Collapse" (DOD, 2009).

For federal facilities under the jurisdiction of the General Services Administration, threat independent guidelines have been developed. The publication "Progressive Collapse Analysis and Design Guidelines for New Federal Office Buildings and Major Modernization Projects" (USGSA, 2003) provides an explicit process that any structural engineer could use to evaluate the progressive collapse potential of a multi-story facility.

Required Strength, Stability, Effective Length, and Second-Order Effects

As previously discussed, the AISC *Specification* requires that the required strength must be less than or equal to the available strength in the design of every member and connection. Chapter C also requires that stability shall be provided for the structure as a whole and each of its elements. Any method that considers the influence of second-order effects, also known as P-delta effects, may be used. Thus, required strengths must be determined including second-order effects, as described in *Specification* Section C2.1. Note that *Specification* Section C2.1(2) permits an amplified first-order analysis as one method of second-order analysis, as provided in Appendix 8.

Second-order effects are the additional forces, moments and displacements resulting from the applied loads acting in their displaced positions as well as the changes from the undeformed to the deformed geometry of the structure. Second-order effects are obtained by considering equilibrium of the structure within its deformed geometry. There are numerous ways of accounting for these effects. The commentary to AISC *Specification* Chapter C provides some guidance on methods of second-order analysis and suggests several benchmark problems for checking the adequacy of analysis methods.

Since 1963, there have been provisions in the AISC Specifications to account for second-order effects. Initially these provisions were embedded in the interaction equations. In past ASD Specifications, second-order effects were accounted for by the term

$$\frac{1}{1-\dfrac{f_a}{F_e'}}$$

found in the interaction equation. In past LRFD Specifications, the factors B_1 and B_2 from Chapter C of those specifications were used to amplify moments to account for second-order effects. B_1 was used to account for the second-order effects due to member curvature and B_2 was used to account for second-order effects due to sidesway. In both Specifications, more exact methods were permitted.

AISC *Specification* Section C1 and Appendix 7 provide three approaches that may be followed.

- The *direct analysis method* is provided in Chapter C. This is the most comprehensive and, as the name suggests, most direct approach to incorporating all necessary factors in the analysis. Through the use of notional loads, reduced stiffness, and a second-order analysis, the design can be carried out with the forces and moments from the analysis and an effective length equal to the member length, K = 1.0. Section C2 of the AISC *Specification* details the requirements for determination of required strengths using this method.
- The *effective length method* is given in AISC *Specification* Appendix 7, Section 7.2. In this method, all gravity-only load cases have a minimum lateral load equal to 0.2% of the story gravity load applied. A second order analysis is carried out and the member strengths of columns and beam-columns are determined using effective lengths, determined by elastic buckling analysis, or more commonly, the alignment charts in the Commentary to the *Specification* when the associated assumptions are satisfied. The *Specification* permits K = 1.0 when the ratio of second order drift to first order drift is less than or equal to 1.1.
- The *first-order analysis method* is given in AISC *Specification* Appendix 7, Section 7.3. With this approach, second-order effects are captured through the application of an additional lateral load equal to at least 0.42% of the story gravity load applied in each load case. No further second-order analysis is necessary. The required strengths are taken as the forces and moments obtained from the analysis and the effective length factor is K = 1.0.

When a second-order analysis is called for in the above methods, AISC *Specification* Section C1 allows any method that properly considers P-delta effects. One such method is amplified first-order elastic analysis provided in *Specification* Appendix 8. This is a modified carry over of the B_1-B_2 approach used in previous LRFD Specifications, which was an extension of the simple approach taken in past ASD Specifications.

The AISC *Specification* fully integrates the provisions for stability with the specified methods of design. For all framing systems, when using the direct analysis method, AISC *Specification* Section C3 provides that the effective length factor, K, for all members can be taken as 1.0 unless a lesser value can be justified by analysis. For the effective length method, AISC *Specification* Appendix 7, Section 7.2.3(a) provides that in braced frames, the effective length factor, K, may be taken as 1.0. For moment frames, Appendix 7, Section 7.2.3(b) requires that a critical buckling analysis to determine the critical buckling stress, F_e, be performed or effective length factors, K, be used. For the first-order analysis method,

Appendix Section 7.3.3 stipulates that the effective length factor, K, be taken as unity for all members. This is discussed in more detail in the Commentary to Appendix 7.

Simplified Determination of Required Strength

When a fast, conservative solution is desired, the following simplification of the effective length method can be used with the aid of Table 2-1. The features of each of the other methods of design for stability are summarized and compared in Table 2-2.

An approximate second-order analysis approach is provided in AISC *Specification* Appendix 8. Where the member amplification (P-δ) factor is small, that is, less than B_2, it is conservative to amplify the total moment and force by B_2. Thus, Equations A-8-1 and A-8-2 become

$$M_r = B_1 M_{nt} + B_2 M_{lt} = B_2 M_u \quad (2\text{-}6)$$

$$P_r = P_{nt} + B_2 P_{lt} = B_2 P_u \quad (2\text{-}7)$$

To use this simplified method, B_1 cannot exceed B_2. For members not subject to transverse loading between their ends, it is very unlikely that B_1 would be greater than 1.0. In addition, the simplified approach is not valid if the amplification factor, B_2, is greater than 1.5, because with the exception of taking $B_1 = B_2$, this simplified method meets the provisions of the effective length method in AISC *Specification* Appendix 7. It is up to the engineer to ensure that the frame is proportioned appropriately to use this simplified approach. In most designs it is not advisable to have a final structure where the second order amplification is greater than 1.5, although it is acceptable. In those cases, one should consider stiffening the structure.

Step 1: Perform a first-order elastic analysis. Gravity load cases must include a minimum lateral load at each story equal to 0.002 times the story gravity load where the story gravity load is the load introduced at that story, independent of any loads from above.

Step 2: Establish the design story drift limit and determine the lateral load that produces that drift. This is intended to be a measure of the lateral stiffness of the structure.

Step 3: Determine the ratio of the total story gravity load to the lateral load determined in Step 2. For an ASD design, this ratio must be multiplied by 1.6 before entering Table 2-1. This ratio is part of the determination of the calculation on the elastic critical buckling strength, $P_{e\,story}$, in AISC *Specification* Equation A-8-7, which includes the parameter R_m. R_m is a minimum of 0.85 for rigid frames and 1.0 for all other frames.

Step 4: Multiply all of the forces and moments from the first-order analysis by the value obtained from Table 2-1. Use the resulting forces and moments as the required strengths for the designs of all members and connections. Note that B_2 must be computed for each story and in each principal direction.

Step 5: For all cases where the multiplier is 1.1 or less, shown shaded in Table 2-1, the effective length may be taken as the member length, $K = 1.0$. For cases where the multiplier is greater than 1.1 but does not exceed 1.5, determine the effective length factor through analysis, such as with the alignment charts of the AISC *Specification*

TABLE 2-1
Multipliers for Use With the Simplified Method

Design Story Drift Limit	Load Ratio from Step 3 (times 1.6 for ASD, 1.0 for LRFD)										
	0	5	10	20	30	40	50	60	80	100	120
H/100	1	1.1	1.1	1.3	**1.5**/1.4	When ratio exceeds 1.5, simplified method requires a stiffer structure.					
H/200	1	1	1.1	1.1	1.2	1.3	**1.4**/1.3	**1.5**/1.4			
H/300	1	1	1	1.1	1.1	1.2	1.2	1.3	**1.5**/1.4		
H/400	1	1	1	1.1	1.1	1.1	1.2	1.2	1.3	**1.4**/1.3	1.5
H/500	1	1	1	1	1.1	1.1	1.1	1.2	1.2	1.3	1.4

Note: Where two values are provided, the value in bold is the value associated with $R_m = 0.85$.

Commentary. For cases where no value is shown for the multiplier, the structure must be stiffened in order to use this simplified approach. Note that the multipliers are the same value for both $R_m = 0.85$ and 1.0 in most instances due to rounding. Where this is not the case, two values are given consistent with the two values of R_m, respectively.

Step 6: Ensure that the drift limit set in Step 2 is not exceeded and revise design as needed.

STABILITY BRACING

Beams, girders and trusses must be restrained against rotation about their longitudinal axes at points of support (a basic assumption stated in the General Provisions of AISC *Specification* Section F1). Additionally, stability bracing with adequate strength and stiffness must be provided consistent with that assumed at braced points in the analysis for frames, columns and beams (see AISC *Specification* Appendix 6). Some guidance for special cases follows.

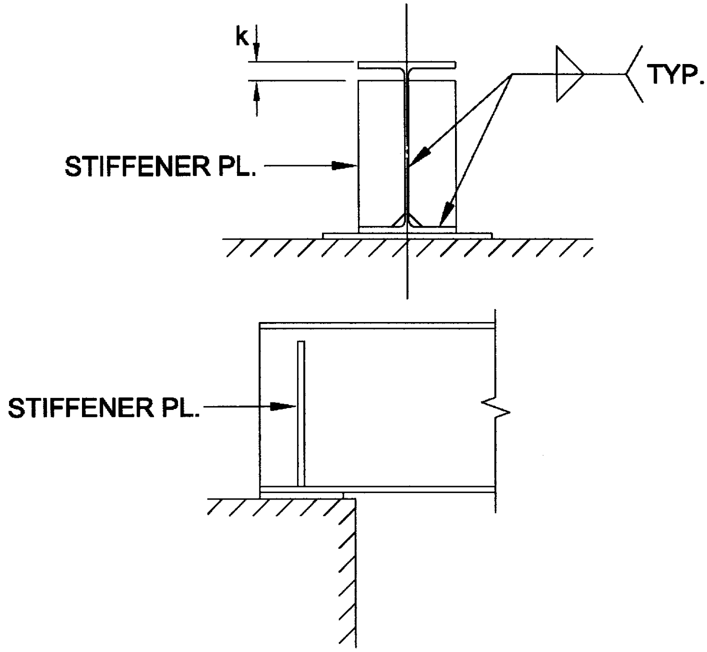
Simple-Span Beams

In general, adequate lateral bracing is provided to the compression flange of a simple-span beam by the connections of infill beams, joists, concrete slabs, metal deck, concrete slabs on metal deck, and similar framing elements.

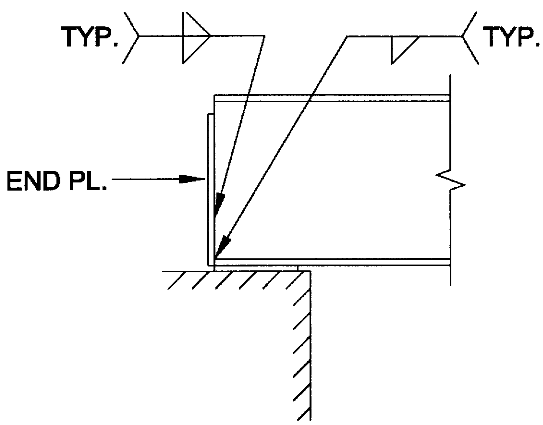
Beam Ends Supported on Bearing Plates

The stability of a beam end supported on a bearing plate can be provided in one of several ways (see Figure 2-1):

1. The beam end can be built into solid concrete or masonry using anchorage devices.
2. The beam top flange can be stabilized through interconnection with a floor or roof system, provided that system is itself anchored to prevent its translation relative to the beam bearing.



(a) Stability provided with transverse stiffeners



(b) Stability provided with an end plate

ANCHOR BEAM AND/OR
BEARING PL. AS REQUIRED

Fig. 2-1. Beam end supported on bearing plate.

3. A top-flange stability connection can be provided.
4. An end-plate or transverse stiffeners located over the bearing plate extending to near the top-flange *k*-distance can be provided. Such stiffeners must be welded to the top of the bottom flange and to the beam web, but need not extend to or be welded to the top flange.

In each case, the beam and bearing plate must also be anchored to the support. For the design of beam bearing plates, see Part 14.

In atypical framing situations, such as when very deep beams are used, the strength and stiffness requirements in AISC *Specification* Appendix 6 can be applied to ensure the stability of the assembly. It may also be possible to demonstrate in a limited number of cases, such as with beams with thick webs and relatively shallow depths, that the beam has been properly designed without providing the details described above. In this case, the beam and bearing plate must still be anchored to the support. In any case, it should be noted that the assembly must also meet the requirements in AISC *Specification* Section J10.

Beams and Girders Framing Continuously Over Columns

Roof framing is commonly configured with cantilevered beams that frame continuously over the tops of columns to support drop-in beams between the cantilevered segments (Rongoe, 1996; CISC, 1989). It is also commonly desirable to provide an assembly in which the intersection of the beam and column can be considered a braced point for the design of both the continuous cantilevering beam and the column top. The required stability can be provided in several ways (see Figure 2-2):

1. When an infill beam frames into the continuous beam at the column top, the required stability normally can be provided by using connection element(s) for the infill beam that cover three-quarters or more of the T-dimension of the continuous beam. Alternatively, connection elements that cover less than three-quarters of the T-dimension of the continuous beam can be used in conjunction with partial-depth stiffeners in the beam web along with a moment connection between the column top and beam bottom to maintain alignment of the beam/column assembly. A cap plate of reasonable proportions and four bolts will normally suffice.

   In either case, note that OSHA requires that, if two framing infill beams share common holes through a column web or the web of a beam that frames continuously over the top of a column,[3] the beam erected first must remain attached while connecting the second.
2. When joists frame into the continuous beam or girder, the required stability normally can be provided by using bottom chord extensions connected to the column top. The resulting continuity moments must be reported to the joist supplier for their use in the design of the joists and bridging. Note that the continuous beam must still be checked for the concentrated force due to the column reaction per AISC *Specification* Section J10.

[3] This requirement applies only at the location of the column, not at locations away from the column.

The position of the bottom chord extension relative to the column cap plate will affect the bottom chord connection detail. When the extension aligns with the cap plate, the load path and force transfer is direct. When the extension is below the column cap plate, the column must be designed to stabilize the beam bottom flange and the connection between the extension and the column must develop the continuity/brace force. When the extension is above the column top, the beam web must have the necessary strength and stiffness to adequately brace the beam bottom/column top.

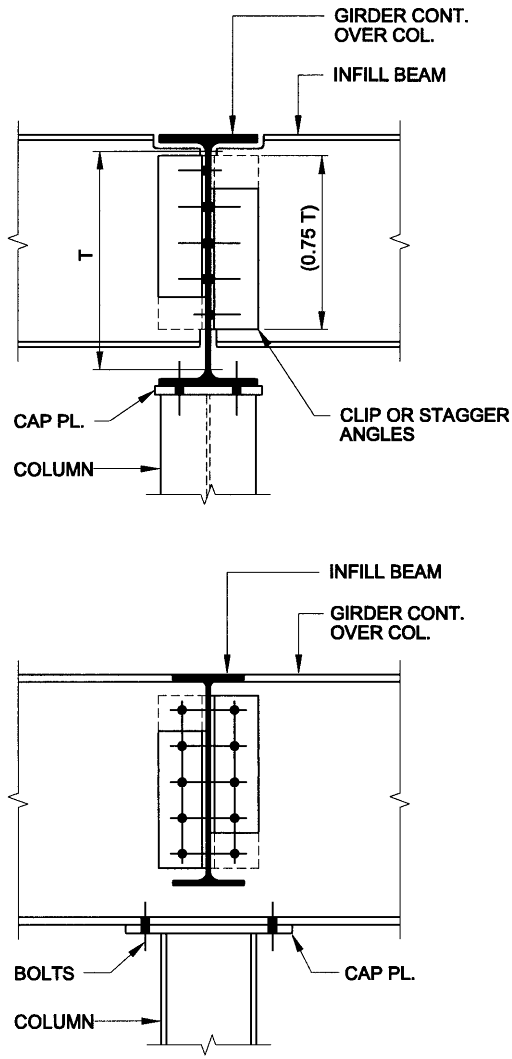


Fig. 2-2a. Beam framing continuously over column top, stability provided with connections of infill beams.

3. If connection of the joist bottom chord extensions to the column must be avoided, the required stability can be provided with a diagonal brace that satisfies the strength and stiffness requirements in AISC *Specification* Appendix 6. Providing a relatively shallow angle with respect to the horizontal can minimize gravity-load effects in the diagonal brace.

   Alternatively, the required stability can be provided with stiffeners in the beam web along with a moment connection between the column top and beam bottom to maintain alignment of the beam/column assembly. A cap plate of reasonable proportions and four bolts will normally suffice.

In atypical framing situations, such as when very deep girders are used, the strength and stiffness requirements in AISC *Specification* Appendix 6 can be applied for both the beam

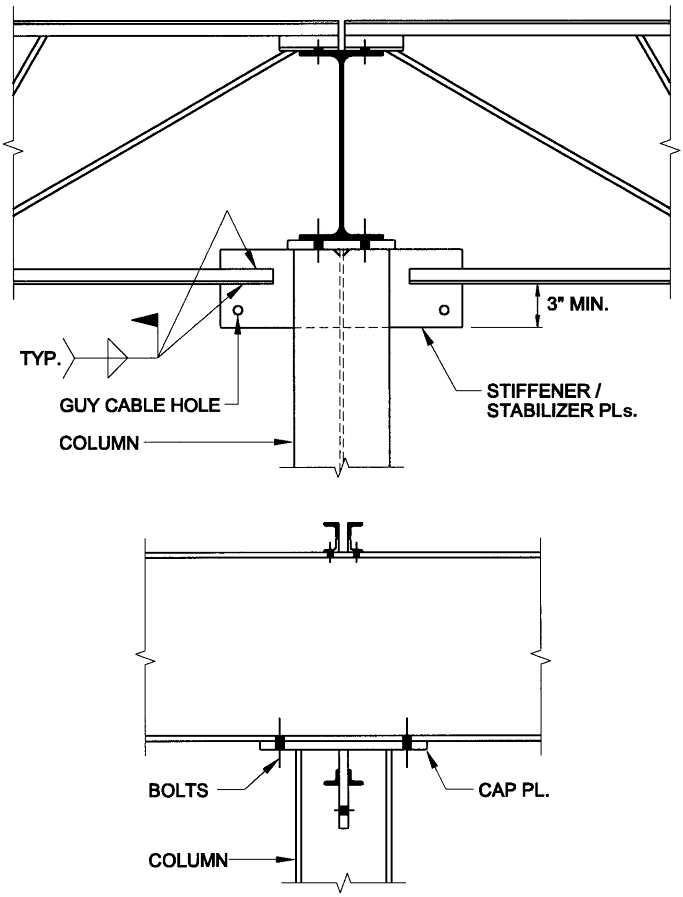

Fig. 2-2b. Beam framing continuously over column top, stability provided with welded joist-chord extensions at column top.

and the column to ensure the stability of the assembly. It may also be possible to demonstrate in a limited number of cases, such as with continuous beams with thick webs and relatively shallow depths, that the column and beam have been properly designed without providing infill beam connections, connected joist extensions, stiffeners, or diagonal braces as described above. In this case, a properly designed moment connection is still required between the beam bottom flange and the column top. In any case, it should be noted that the assembly must also meet the requirements in AISC *Specification* Section J10.

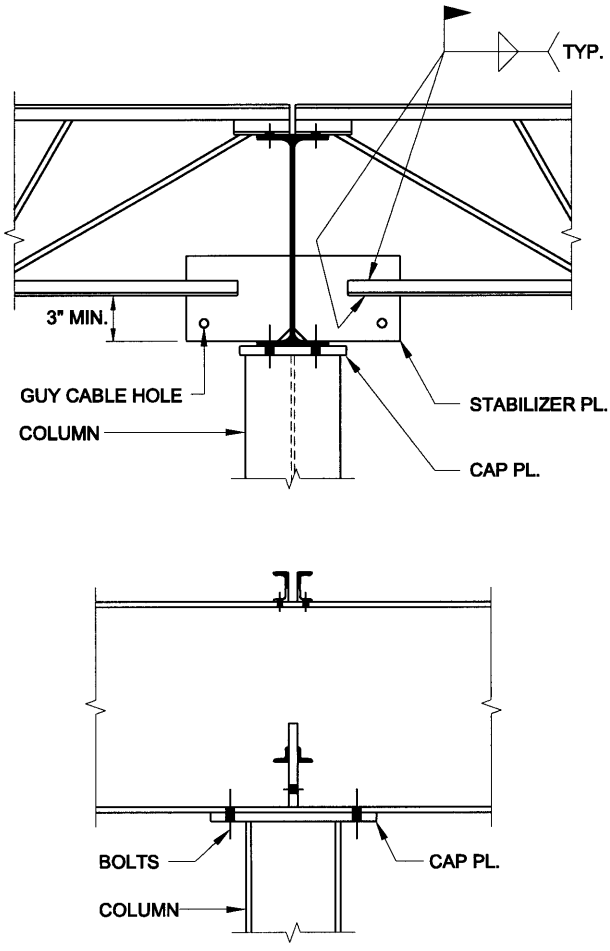

Fig. 2-2c. Beam framing continuously over column top, stability provided with welded joist-chord extensions above column top.

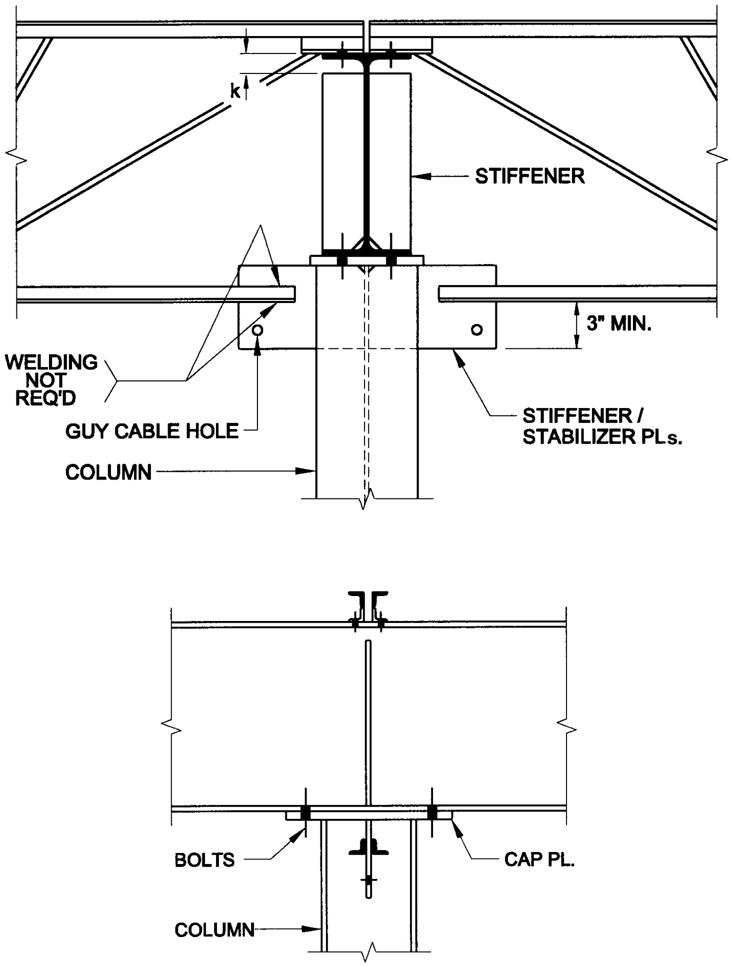

Fig. 2-2d. Beam framing continuously over column top, stability provided with transverse stiffeners, joist chord extensions located at column top not welded.

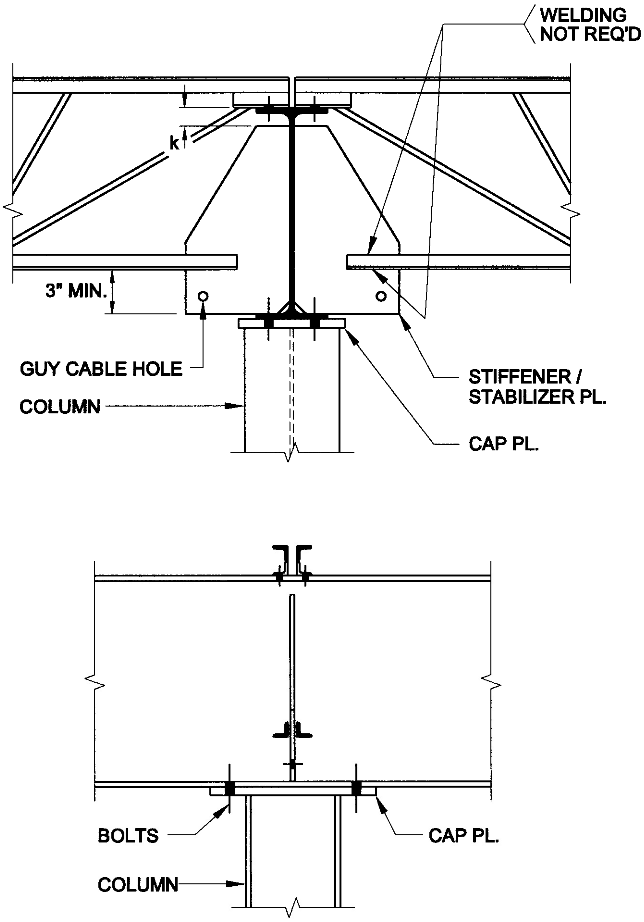

Fig. 2-2e. Beam framing continuously over column top, stability provided with stiffener plates, joist-chord extensions located above column top not welded.

PROPERLY SPECIFYING MATERIALS

Availability

The general availability of structural shapes, HSS and pipe can be determined by checking the AISC database of available structural steel shapes at **www.aisc.org/SteelAvailability**. Generally, where many producers are listed, it is an indication that the particular shape is commonly available. However, except for the larger shapes, when only one or two producers are listed, it is prudent to consider contacting a steel fabricator to determine availability.

Material Specifications

Applicable material specifications are as shown in the following tables:

- Structural shapes in Table 2-3
- Plate and bar products in Table 2-4
- Fastening products in Table 2-5

Preferred material specifications are indicated in black shading. Other applicable material specifications are as shown in grey shading. The availability of grades other than the preferred material specification should be confirmed prior to their specification.

Cross-sectional dimensions and production tolerances are addressed as indicated under "Standard Mill Practices" in Part 1.

Other Products

Anchor rods

Although the AISC *Specification* permits other materials for use as anchor rods, ASTM F1554 is the preferred specification, since all anchor rod production requirements are together in a single specification. ASTM F1554 provides three grades, namely 36 ksi, 55 ksi and 105 ksi. All Grade 36 rods are weldable. Grade 55 rods are weldable only when they are made per Supplementary Requirement S1. The project specifications must indicate if the material is to conform to Supplementary Requirement S1. As a heat-treated material, Grade 105 rods cannot be welded. Grade 105 should be used only for limited applications that require its high strength. For more information, refer to AISC Design Guide 1, *Base Plate and Anchor Rod Design* (Fisher and Kloiber, 2006).

Raised-Pattern Floor Plates

ASTM A786 is the standard specification for rolled steel floor plates. As floor-plate design is seldom controlled by strength considerations, ASTM A786 "commercial grade" is commonly specified. If so, per ASTM A786-05 Section 5.1.3, "the product will be supplied 0.33% maximum carbon by heat analysis, and without specified mechanical properties." Alternatively, if a defined strength level is desired, ASTM A786 raised-pattern floor plate can be ordered to a defined plate specification, such as ASTM A36, A572 or A588; see ASTM A786 Sections 5.1.3, 7.1 and 8.

Sheet and Strip

Sheet and strip products, which are generally thinner than structural plate and bar products are produced to such ASTM specifications as A570, A606 or A607 (see Table 2-3),

Filler Metal

The appropriate filler metal for structural steel is as summarized in ANSI/AWS D1.1: 2010 Table 3.1 for the various combinations of base metal specification and grade and electrode specification. Weld strengths in this Manual are based upon a tensile strength level of 70 ksi.

Steel Headed Stud Anchors

As specified in ANSI/AWS D1.1 Chapter 7 (Section 7.2.6 and Table 7.1), Type B shear stud connectors (referred to in the AISC *Specification* as steel headed stud anchors) made from ASTM A108 material are used for the interconnection of steel and concrete elements in composite construction (F_u = 65 ksi).

Open Web Steel Joists

The AISC *Code of Standard Practice* does not include steel joists in its definition of structural steel. Steel joists are designed and fabricated per the requirements of specifications published by the Steel Joist Institute. Refer to SJI literature for further information.

Castellated Beams

Castellated beams, also known as cellular beams, are members constructed by cutting along a staggered pattern down the web of a wide-flange member, offsetting the resulting pieces such that the deepest points of the cut are in contact, and welding the two pieces together, thereby creating a member with holes along its web. Castellated beams are currently designed and fabricated as a proprietary product. For more information, contact the manufacturer.

Steel Castings and Forgings

Steel castings are specified as ASTM A27 Grade 65-35 or ASTM A216 Grade 80-35. Steel forgings are specified as ASTM A668.

Forged Steel Structural Hardware

Forged steel structural hardware products, such as clevises, turnbuckles, eye nuts and sleeve nuts, are occasionally used in building design and construction. These products are generally forged according to ASTM A668 Class A requirements. ASTM A29, Grade 1035 material is commonly used in the manufacture of clevises and turnbuckles. ASTM A29, Grade 1030 material is commonly used in the manufacture of steel eye nuts and steel eye bolts. ASTM A29 Grade 1018 material is commonly used in the manufacture of sleeve nuts. Other products, such as steel rod ends, steel yoke ends and pins, cotter pins, and coupling nuts are commonly provided generically as "carbon steel."

The dimensional and strength characteristics of these devices are fully described in the literature provided by their manufacturer. Note that manufacturers usually provide strength characteristics in terms of a "safe working load" with a safety factor as high as 5, assuming that the product will be used in rigging or similar applications subject to dynamic loading. The manufacturer's safe working load may be overly conservative for permanent installations and similar applications subject to static loading only.

If desired, the published safe working load can be converted into an available strength with reliability consistent with that of other statically loaded structural materials. In this case, the nominal strength, R_n, is determined as:

$$R_n = (\textit{safe working load}) \times (\textit{manufacturer's safety factor}) \tag{2-8}$$

and the available strength, ϕR_n or R_n/Ω, is determined using

$$\phi = 0.50 \text{ (LRFD)} \qquad \Omega = 3.00 \text{ (ASD)}$$

Crane Rails

Crane rails are furnished to ASTM A759, ASTM A1, and/or manufacturer's specifications and tolerances.

Most manufacturers chamfer the top and sides of the crane-rail head at the ends unless specified otherwise to reduce chipping of the running surfaces. Often, crane rails are ordered as end-hardened, which improves the resistance of the crane-rail ends to impact that occurs as the moving wheel contacts it during crane operation. Alternatively, the entire rail can be ordered as heat-treated. When maximum wheel loading or controlled cooling is needed, refer to manufacturers' catalogs. Purchase orders for crane rails should be noted "for crane service."

Light 40-lb rails are available in 30-ft lengths, 60-lb rails in 30-, 33- or 39-ft lengths, standard rails in 33- or 39-ft lengths and crane rails up to 80 ft. Consult manufacturer for availability of other lengths. Rails should be arranged so that joints on opposite sides of the crane runway will be staggered with respect to each other and with due consideration to the wheelbase of the crane. Rail joints should not occur at crane girder splices. Odd lengths that must be included to complete a run or obtain the necessary stagger should be not less than 10 ft long. Rails are furnished with standard drilling in both standard and odd lengths unless stipulated otherwise on the order.

CONTRACT DOCUMENT INFORMATION

Design Drawings, Specifications and Other Contract Documents

CASE Document 962D, *A Guideline Addressing Coordination and Completeness of Structural Construction Documents* (CASE, 2003), provides comprehensive guidance on the preparation of structural design drawings.

Most provisions in the AISC *Specification*, RCSC *Specification*, AWS D1.1, and the AISC *Code of Standard Practice* are written in mandatory language. Some provisions require the communication of information in the contract documents, some provisions are invoked only when specified in the contract documents, and some provisions require the approval of the owner's designated representative for design if they are to be used. Following is a summary of these provisions in the AISC *Specification*, RCSC *Specification*, and AISC *Code of Standard Practice*.

Required Information

The following communication of information is required in the contract documents:

1. Required drawing information, per AISC *Code of Standard Practice* Sections 3.1 and 3.1.1 through 3.1.6. and RCSC *Specification* Section 1.4 (bolting products and joint type)
2. Drawing numbers and revision numbers, per AISC *Code of Standard Practice* Section 3.5
3. Structural system description, per AISC *Code of Standard Practice* Section 7.10.1
4. Installation schedule for nonstructural steel elements in the structural system, per AISC *Code of Standard Practice* Section 7.10.2
5. Project schedule, per AISC *Code of Standard Practice* Section 9.5.1

Information Required Only When Specified

The following provisions are invoked only when specified in the contract documents:

1. Special material notch-toughness requirements, per AISC *Specification* Section A3.1c and Section A3.1d
2. Special connections requiring pretension, per AISC *Specification* Section J1.10
3. Bolted joint requirements, per AISC *Specification* Section J3.1 and RCSC *Specification* Section 1.4
4. Special cambering considerations, per AISC *Specification* Section L2
5. Special contours and finishing requirements for thermal cutting, per AISC *Specification* Sections M2.2 and M2.3, respectively
6. Corrosion protection requirements, if any, per AISC *Specification* Section M3 and AISC *Code of Standard Practice* Sections 6.5, 6.5.2 and 6.5.3
7. Responsibility for field touch-up painting, if painting is specified, per AISC *Specification* Section M4.6 and AISC *Code of Standard Practice* Section 6.5.4
8. Special quality control and inspection requirements, per AISC *Specification* Chapter N and AISC *Code of Standard Practice* Sections 8.1.3, 8.2 and 8.3
9. Evaluation procedures, per AISC *Specification* Section B6
10. Fatigue requirements, if any, per AISC *Specification* Section B3.9
11. Tolerance requirements other than those specified in the AISC *Code of Standard Practice*, per *Code of Standard Practice* Section 1.9
12. Designation of each connection as Option 1, 2 or 3, and identification of requirements for substantiating connection information, if any, per AISC *Code of Standard Practice* Section 3.1.2
13. Specific instructions to address items differently, if any, from requirements in the AISC *Code of Standard Practice*, per *Code of Standard Practice* Section 1.1
14. Submittal schedule for shop and erection drawings, per AISC *Code of Standard Practice* Section 4.2
15. Mill order timing, special mill testing, and special mill tolerances, per AISC *Code of Standard Practice* Sections 5.1, 5.2 and 5.2, respectively
16. Removal of backing bars and runoff tabs, per AISC *Code of Standard Practice* Section 6.3.2
17. Special erection mark requirements, per AISC *Code of Standard Practice* Section 6.6.1

18. Special delivery and erection sequences, per AISC *Code of Standard Practice* Sections 6.7.1 and 7.1, respectively
19. Special field splice requirements, per AISC *Code of Standard Practice* Section 6.7.4
20. Specials loads to be considered during erection, per AISC *Code of Standard Practice* Section 7.10.3
21. Special safety protection treatments, per AISC *Code of Standard Practice* Section 7.11.1
22. Identification of adjustable items, per AISC *Code of Standard Practice* Section 7.13.1.3
23. Cuts, alterations and holes for other trades, per AISC *Code of Standard Practice* Section 7.15
24. Revisions to the contract, per AISC *Code of Standard Practice* Section 9.3
25. Special terms of payment, per AISC *Code of Standard Practice* Section 9.6
26. Identification of architecturally exposed structural steel, per AISC *Code of Standard Practice* Section 10

Approvals Required

The following provisions require the approval of the owner's designated representative for design if they are to be used:

1. Bolted-joint-related approvals per RCSC *Specification* Commentary Section 1.4
2. Use of electronic or other copies of the design drawings by the fabricator, per AISC *Code of Standard Practice* Section 4.3
3. Use of stock materials not conforming to a specified ASTM specification, per AISC *Code of Standard Practice* Section 5.2.3
4. Correction of errors, per AISC *Code of Standard Practice* Section 7.14
5. Inspector-recommended deviations from contract documents, per AISC *Code of Standard Practice* Section 8.5.6
6. Contract price adjustment, per AISC *Code of Standard Practice* Section 9.4.2

Establishing Criteria for Connections

AISC *Code of Standard Practice* Section 3.1.2 provides the following three methods for the establishment of connection requirements.

In the first method, the complete design of all connections is shown in the structural design drawings. In this case, AISC *Code of Standard Practice* Commentary Section 3.1.2 provides a summary of the information that must be included in the structural design drawings. This method has the advantage that there is no need to provide connection loads, since the connections are completely designed in the structural design drawings. Additionally, it favors greater accuracy in the bidding process, since the connections are fully described in the contract documents.

In the second method, the fabricator is allowed to select or complete the connections while preparing the shop and erection drawings, using the information provided by the owner's designated representative for design per AISC *Code of Standard Practice* Section 3.1.2. In this case, AISC *Code of Standard Practice* Commentary Section 3.1.2 clarifies the intention that connections that can be selected or completed by the fabricator include those for which tables appear in the contract documents or the Manual. Other connections should be shown in detail in the structural design drawings.

In the third method, connections are designated in the contract documents to be designed by a licensed professional engineer working for the fabricator. The AISC *Code of Standard Practice* sets forth detailed provisions that, in the absence of contract provisions to the contrary, serve as the basis of the relationships among the parties. One feature of these provisions is that the fabricator is required to provide representative examples of connection design documentation early in the process, and the owner's designated representative for design is obliged is to review these submittals for conformity with the requirements of the contract documents. These early submittals are required in an attempt to avoid additional costs and/or delays as the approval process proceeds through subsequent shop drawings with connections developed from the original representative samples.

Methods one and two have the advantage that the fabricator's standard connections normally can be used, which often leads to project economy. However, the loads or other connection design criteria must be provided in the structural design drawings. Design loads and required strengths for connections should be provided in the structural design drawings and the design method used in the design of the frame (ASD or LRFD) must be indicated on the drawings.

In all three methods, the resulting shop and erection drawings must be submitted to the owner's designated representative for design for review and approval. As stated in the AISC *Code of Standard Practice* Section 4.4.1, the approval of shop and erection drawings constitutes "confirmation that the Fabricator has correctly interpreted the Contract Documents" and that the reviewer has "reviewed and approved the Connection details shown in the Shop and Erection Drawings." Following is additional guidance for the communication of connection criteria to the connection designer.

Simple Shear Connections

The full force envelope should be given for each simple shear connection. Because of the potential for overestimation and underestimation inherent in approximate methods (Thornton, 1995), actual beam end reactions should be indicated on the design drawings. The most effective method to communicate this information is to place a numeric value at each end of each span in the framing plans.

In the past, beam end reactions were sometimes specified as a percentage of the tabulated uniform load in Manual Part 3. This practice can result in either over- or under-specification of connection reactions and should not be used. The inappropriateness of this practice is illustrated in the following examples.

Over-estimation:

1. When beams are selected for serviceability considerations or for shape repetition, the uniform load tables will often result in heavier connections than would be required by the actual design loads.
2. When beams have relatively short spans, the uniform load tables will often result in heavier connections than would be required by the actual design loads. If not addressed with the accurate load, many times the heavier connections will require extension of the connection below the bottom flange of the supported member, requiring that the flange on one or both sides of the web to be cut and chipped, a costly process.

Under-estimation:

1. When beams support other framing beams or other concentrated loads occur on girders supporting beams, the end reactions can be higher than 50% of the total uniform load.
2. For composite beams, the end reactions can be higher than 50% of the total uniform load. The percentage requirement can be increased for this condition, but the resulting approach is still subject to the above considerations.

Moment Connections

The full force envelope should be given for each moment connection. If the owner's designated representative for design can select the governing load combination, its effect alone should be provided. Otherwise, the effects of all appropriate load combinations should be indicated. Additionally, the maximum moment imbalance should also be given for use in the check of panel-zone web shear.

Because of the potential for overestimation—and underestimation—inherent in approximate methods, it is recommended that the actual beam end reactions (moment, shear and other reactions, if any) be indicated in the structural design drawings. The most effective method to do so may be by tabulation for each joint and load combination.

Although not recommended, beam end reactions are sometimes specified by more general criteria, such as by function of the beam strength. It should be noted, however, that there are several situations in which this approach is not appropriate. For example:

1. When beams are selected for serviceability considerations or for shape repetition, this approach will often result in heavier connections than would be required by the actual design loads.
2. When the column(s) or other members that frame at the joint could not resist the forces and moments determined from the criteria so specified, this approach will often result in heavier connections than would be required by the actual design loads.

In some cases, the structural analysis may require that the actual connections be configured to match the assumptions used in the model. For example, it may be appropriate to release weak-axis moments in a beam-column joint where only strong-axis beam moment strength is required. Such requirements should be indicated in the structural design drawings.

Horizontal and Vertical Bracing Connections

The full force envelope should be given for each bracing-member end connection. If the owner's designated representative for design can select the governing load combination for the connection, its effect alone should be provided. Otherwise, the effects of all appropriate load combinations should be indicated in tabular form. This approach will allow a clear understanding of all of the forces on any given joint.

Because of the potential for overestimation—and underestimation—inherent in approximate methods, it is recommended that the actual reactions at the bracing member end (axial force and other reactions, if any) be indicated in the structural design drawings. It is also recommended that transfer forces, if any, be so indicated. The most effective method to do so may be by tabulation for each bracing member end and load combination.

Although not recommended, bracing member end reactions can be specified by more general criteria, such as by maximum member forces (tension or compression) or as a function of the member strength. It should be noted, however, that there are several situations in which such approaches are not appropriate. For example:

1. The specification of maximum member forces does not permit a check of the member forces at a joint if there are different load combinations governing the member designs at that joint. Nor does it reflect the possibility of load reversal as it may influence the design.
2. The specification of a percentage of member strength may not properly account for the interaction of forces at a joint or the transfer force through the joint. Additionally, it may not allow for a cross-check of all forces at a joint.

In either case, this approach will often result in heavier connections than would be required by the actual design loads.

Bracing connections may involve the interaction of gravity and lateral loads on the frame. In some cases, such as V- and inverted V-bracing (also known as Chevron bracing), gravity loads alone may govern design of the braces and their connections. Thus, clarity in the specification of loads and reactions is critical to properly consider the potential interaction of gravity and lateral loads at floors and roofs.

Strut and Tie Connections

Floor and roof members in braced bays and adjacent bays may function as struts or ties in addition to carrying gravity loads. Therefore the recommendations for simple shear connections and bracing connections above apply in combination.

Truss Connections

The recommendations for horizontal and vertical bracing connections above also apply in general to bracing connections with the following additional comments.

Note that it is not necessary to specify a minimum connection strength as a percent of the member strength as a default. However, when trusses are shop assembled or field assembled on the ground for subsequent erection, consideration should be given to the loads that will be induced during handling, shipping and erection.

Column Splices

Column splices may resist moments, shears and tensions in addition to gravity forces. Typical column splices are discussed in Part 14. As in the case of the other connections discussed above, unless the column splices are fully designed in the construction documents, forces and moments for the splice designs should be provided in the construction documents. Since column splices are located away from the girder/column joint and moments vary in the height of the column, an accurate assessment of the forces and moments at the column splices will usually significantly reduce their cost and complexity.

CONSTRUCTABILITY

Constructability is a relatively new word for a well established idea. The design, detailing, fabrication and erection of structural steel is a process which in the end needs to result in a safe and economical steel frame. Building codes and the AISC *Specification* address strength and structural integrity. Constructability addresses the need for global economy in the fabricated and erected steel frame. Constructability must be "designed in," influencing decision making at all steps of the design process, from framing system selection, though member design, to connection selection and design. Constructability demands attention to detail and requires the designer to think ahead to the fabrication and erection of the steel frame. The goal is to design a steel frame that is relatively easy to detail, fabricate and erect. AISC provides guidance to the design community through its many publications and presentations, including the recently published Design Guide 23, *Constructability of Structural Steel Buildings* (Ruby, 2008).

Constructability focuses on such issues as framing layout, the number of pieces in an area of framing, three-dimensional connection geometry, swinging in clearances, access to bolts, and access to welds. It involves the acknowledgement that numerous, seemingly small decisions can have an effect on the overall economy of the final erected steel frame. Fabricators and erectors have the knowledge that can assist in the design of constructible steel frames. Designers should seek their counsel.

TOLERANCES

The effects of mill, fabrication and erection tolerances all require consideration in the design and construction of structural steel buildings. However, the accumulation of the mill tolerances and fabrication tolerances shall not cause the erection tolerances to be exceeded, per AISC *Code of Standard Practice* Section 7.12.

Mill Tolerances

Mill tolerances are those variations that could be present in the product as-delivered from the rolling mill. These tolerances are given as follows:

1. For structural shapes and plates, see ASTM A6.
2. For HSS, see ASTM A500 (or other applicable ASTM specification for HSS).
3. For pipe, see ASTM A53.

A summary of standard mill practices is also given in Part 1.

Fabrication Tolerances

Fabrication tolerances are generally provided in AISC *Specification* Section M2 and AISC *Code of Standard Practice* Section 6.4. Additional requirements that govern fabrication are as follows:

1. Compression joint fit-up, per AISC *Specification* Section M4.4
2. Roughness limits for finished surfaces, per AISC *Code of Standard Practice* Section 6.2.2
3. Straightness of projecting elements of connection materials, per AISC *Code of Standard Practice* Section 6.3.1
4. Finishing requirements at locations of removal of run-off tabs and similar devices, per AISC *Code of Standard Practice* Section 6.3.2

Erection Tolerances

Erection tolerances are generally provided in AISC *Specification* Section M4 and AISC *Code of Standard Practice* Section 7.13. Note that the tolerances specified therein are predicated upon the proper installation of the following items by the owner's designated representative for construction:

1. Building lines and benchmarks, per AISC *Code of Standard Practice* Section 7.4
2. Anchorage devices, per AISC *Code of Standard Practice* Section 7.5
3. Bearing devices, per AISC *Code of Standard Practice* Section 7.6
4. Grout, per AISC *Code of Standard Practice* Section 7.7

Building Façade Tolerances

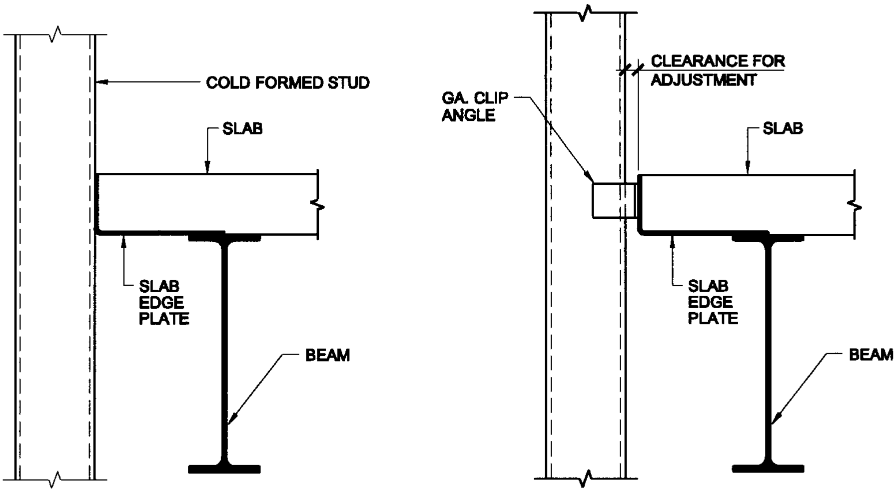
The preceding mill, fabrication and erection tolerances can be maintained with standard equipment and workmanship. However, the accumulated tolerances for the structural steel and the building façade must be accounted for in the design so that the two systems can be properly mated in the field. In the steel frame, this is normally accomplished by specifying adjustable connections in the contract documents, per AISC *Code of Standard Practice* Section 7.13.1.3. This section has three subsections. Subsection (a) addresses the vertical position of the adjustable items, subsection (b) addresses the horizontal position of the adjustable items, and subsection (c) addresses alignment of adjustable items at abutting ends.

The required adjustability normally can be determined from the range of adjustment in the building façade anchor connections, tolerances for the erection of the building façade, and the accumulation of mill, fabrication and erection tolerances at the mid-span point of the spandrel beam. The actual locations of the column bases, the actual slope of the columns and the actual sweep of the spandrel beam all affect the accumulation of tolerances in the structural steel at this critical location. These conditions must be reflected in details that will allow successful erection of the steel frame and the façade, if each of these systems is properly constructed within its permitted tolerance envelope.

Figures 2-3a, 2-4a and 2-5a illustrate details that are not recommended because they do not provide for adjustment. Figures 2-3b, 2-4b and 2-5b illustrate recommended alternative details that do provide for adjustability. Note that diagonal structural and stability bracing elements have been omitted in these details to improve the clarity of presentation regarding adjustability. Also, note that all elements beyond the slab edge are normally not structural steel, per AISC *Code of Standard Practice* Section 2.2, and are shown for the purposes of illustration only.

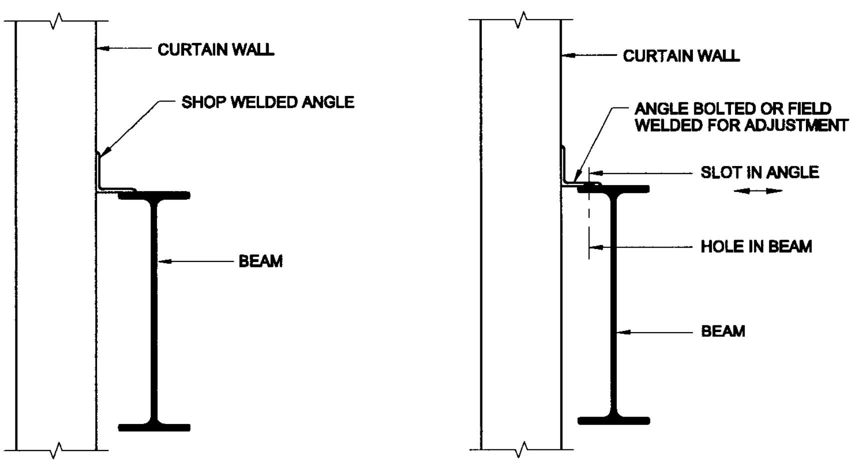
The bolted details in Figures 2-4b and 2-5b can be used to provide field adjustability with slotted holes as shown. Further adjustability can be provided in these details, if necessary, by removing the bolts and clamping the connection elements for field welding. Alternatively, when the slab edge angle or plate in Figure 2-4b is shown as field welded and identified as adjustable in the contract documents, it can be provided to within a horizontal tolerance of $\pm 3/8$ in., per AISC *Code of Standard Practice* Section 7.13.1.3. However, if the item was not shown as field welded and identified as adjustable in the contract documents, it would likely be attached in the shop or attached in the field to facilitate the concrete pour and not be suitable to provide for the necessary adjustment. The details in Figures 2-3b and 2-4b do not readily permit vertical adjustment of the adjustable material. However, the vertical position tolerance of $\pm 3/8$ in. is less than the tolerance for the position of the spandrel member itself, see AISC *Code of Standard Practice* Section 7.13.1.2(b). The manufacturing tolerance for camber in the spandrel member is set by ASTM A6, as summarized in Table 1-22. The ASTM A6 limit for camber is $1/8$ in. per 10 ft of length, thus, in most situations the vertical position tolerance in AISC *Code of Standard Practice* Section 7.13.1.3(b) should be achieved indirectly. In general, spandrel members should not be cambered. Deflection of spandrel members should be controlled by member stiffness. Figure 2-5b shows a detail in which both horizontal and vertical adjustment can be achieved.

With adjustable connections specified in design and provided in fabrication, actions taken on the job site will allow for a successful façade installation. Per the AISC *Code of Standard Practice* definition of established column line (see *Code of Standard Practice* Glossary),



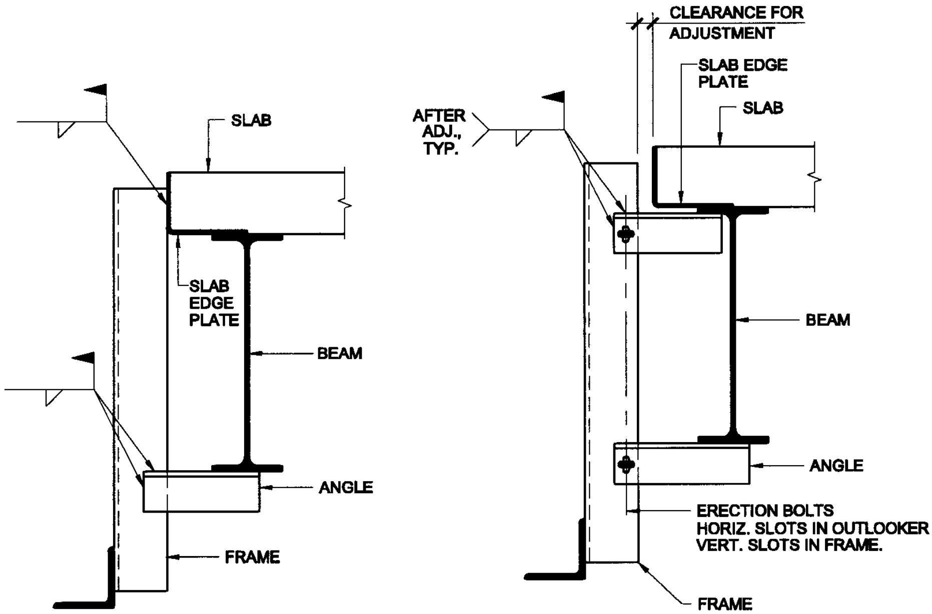
(a) Without adjustment (not recommended) *(b) With adjustment (recommended)*

Fig. 2-3. Attaching cold-formed steel façade systems to structural steel framing.



(a) Without adjustment (not recommended) *(b) With adjustment (recommended)*

Fig. 2-4. Attaching curtain wall façade systems to structural steel framing.



(a) Without adjustment (not recommended) *(b) With adjustment (recommended)*

Fig. 2-5. Attaching masonry façade systems to structural steel framing.

proper placement of this line by the owner's designated representative for construction based upon the actual column-center locations will assure that all subcontractors are working from the same information. When sufficient adjustment cannot be accommodated within the adjustable connections provided, a common solution is to allow the building façade to deviate (or drift) from the theoretical location to follow the as-built locations of the structural steel framing and concrete floor slabs. A survey of the as-built locations of these elements can be used to adjust the placement of the building façade accordingly. In this case, the adjustable connections can serve to ensure that no abrupt changes occur in the façade.

QUALITY CONTROL AND QUALITY ASSURANCE

Prior to 2010, quality control and quality assurance were addressed in the contract documents, Chapter M of the AISC *Specification*, and building codes. In the 2010 AISC *Specification*, Chapter N, entitled Quality Control and Quality Assurance, has been added. This chapter distinguishes between quality control, which is the responsibility of the fabricator and erector, and quality assurance, which is the responsibility of the owner, usually through third party inspectors. The new provisions bring together requirements from diverse sources of quality control (QC) and quality assurance (QA), so that plans for QC and QA can be established on a project specific basis. Chapter N provides tabulated lists of inspection tasks for both QC and QA. As in the case of the AISC *Seismic Provisions*, these tasks are characterized as either "observe" or "perform." Tasks identified as "observe" are general and random. Tasks identified as "perform" are specific to the final acceptance of an item in the work. The characterization of tasks as observe and perform is a substitute for the distinction between periodic and continuous inspection used in other codes and standards, such as the *International Building Code*.

CAMBERING, CURVING AND STRAIGHTENING

Beam Camber and Sweep

Camber denotes a curve in the vertical plane. Sweep denotes a curve in the horizontal plane. Camber and sweep occur naturally in members as received from the mill. The deviation of the member from straight must be within the mill tolerances specified in ASTM A6/A6M.

When required by the contract documents, cambering and curving to a specified amount can be provided by the fabricator per AISC *Code of Standard Practice* Sections 6.4.2 and 6.4.4, either by cold bending or by hot bending.

Cambering and curving induce residual stresses similar to those that develop in rolled structural shapes as elements of the shape cool from the rolling temperature at different rates. These residual stresses do not affect the available strength of structural members, since the effect of residual stresses is considered in the provisions of the AISC *Specification*.

Cold Bending

The inelastic deformations required in common cold bending operations, such as for beam cambering, normally fall well short of the strain-hardening range. Specific limitations on cold-bending capabilities should be obtained from those that provide the service and from *Cold Bending of Wide-Flange Shapes for Construction* (Bjorhovde, 2006). However, the following general guidelines may be useful in the absence of other information:

1. The minimum radius for camber induced by cold bending in members up to a nominal depth of 30 in. is between 10 and 14 times the depth of the member. Deeper members may require a larger minimum radius.
2. Cold bending may be used to provide curving in members to practically any radius desired.
3. A minimum length of 25 ft is commonly practical due to manufacturing/fabrication equipment.

When curvatures and the resulting inelastic deformations are significant and corrective measures are required, the effects of cold work on the strength and ductility of the structural steels largely can be eliminated by thermal stress relief or annealing.

Hot Bending

The controlled application of heat can be used in the shop and field to provide camber or curvature. The member is rapidly heated in selected areas that tend to expand, but are restrained by the adjacent cooler areas, causing inelastic deformations in the heated areas and a change in the shape of the cooled member.

The mechanical properties of steels are largely unaffected by such heating operations, provided the maximum temperature does not exceed the temperature limitations given in AISC *Specification* Section M2.1. Temperature-indicating crayons or other suitable means should be used during the heating process to ensure proper regulation of the temperature.

Heat curving induces residual stresses that are similar to those that develop in hot-rolled structural shapes as they cool from the rolling temperature because all parts of the shape do not cool at the same rate.

Truss Camber

Camber is provided in trusses, when required, by the fabricator per AISC *Code of Standard Practice* Section 6.4.5, by geometric relocation of panel points and adjustment of member lengths based upon the camber requirements as specified in the contract documents.

Straightening

All structural shapes are straightened at the mill after rolling, either by rotary or gag straightening, to meet the aforementioned mill tolerances. Similar processes and/or the controlled application of heat can be used in the shop or field to straighten a curved or distorted member. These processes are normally applied in a manner similar to those used to induce camber and curvature and described above.

FIRE PROTECTION AND ENGINEERING

Provisions for structural design for fire conditions are found in Appendix 4 of the AISC *Specification*. Complete coverage of fire protection and engineering for steel structures is included in AISC Design Guide 19, *Fire Resistance of Structural Steel Framing* (Ruddy et al., 2003).

CORROSION PROTECTION

In building structures, corrosion protection is not required for steel that will be enclosed by building finish, coated with a contact-type fireproofing, or in contact with concrete. When enclosed, the steel is trapped in a controlled environment and the products required for corrosion are quickly exhausted, as indicated in AISC *Specification* Commentary Section M3. A similar situation exists when steel is fireproofed or in contact with concrete. Accordingly, shop primer or paint is not required unless specified in the contract documents, per AISC *Specification* Section M3.1. Per AISC *Code of Standard Practice* Section 6.5, steel that is to remain unpainted need only be cleaned of heavy deposits of oil and grease by appropriate means after fabrication.

Corrosion protection is required, however, in exterior exposed applications. Likewise, steel must be protected from corrosion in aggressively corrosive applications, such as a paper processing plant, a structure with oceanfront exposure, or when temperature changes can cause condensation. Corrosion should also be considered when connecting steel to dissimilar metals. Guidance on steel compatibility with metal fasteners is provided in Table 2-7.

When surface preparation other than the cleaning described above is required, an appropriate grade of cleaning should be specified in the contract documents according to the Society for Protective Coatings (SSPC). A summary of the SSPC surface preparation specifications (SSPC, 2000) is provided in Table 2-8. SSPC SP 2 is the normal grade of cleaning when cleaning is required.

For further information, refer to the publications of SSPC, the American Galvanizers Association (AGA), and the National Association of Corrosion Engineers International (NACE).

RENOVATION AND RETROFIT OF EXISTING STRUCTURES

The provisions in AISC *Specification* Section B6 govern the evaluation of existing structures. Historical data on available steel grades and hot-rolled structural shapes, including dimensions and properties, is available in AISC Design Guide 15, *Rehabilitation and Retrofit Guide* (Brockenbrough, 2002) and the companion database of historic shape properties from 1873-1999 **available at www.aisc.org**. See also Ricker (1988) and Tide (1990).

THERMAL EFFECTS

Expansion and Contraction

The average coefficient of expansion, ε, for structural steel between 70 °F and 100 °F is 0.0000065 for each °F (Camp et al., 1951). This value is a reasonable approximation of the coefficient of thermal expansion for temperatures less than 70 °F. For temperatures from 100 to 1,200 °F, the change in length per unit length per °F, ε, is:

$$\varepsilon = (6.1 + 0.0019t)10^{-6} \quad (2\text{-}9)$$

where t is the initial temperature in °F. The coefficients of expansion for other building materials can be found in Table 17-11.

Although buildings are typically constructed of flexible materials, expansion joints are often required in roofs and the supporting structure when horizontal dimensions are large. The maximum distance between expansion joints is dependent upon many variables, including ambient temperature during construction and the expected temperature range during the lifetime of the building.

Figure 2-6 (Federal Construction Council, 1974) provides guidance based on design temperature change for maximum spacing of structural expansion joints in beam-and-column-framed buildings with pinned column bases and heated interiors. The report includes data for numerous cities and gives five modification factors to be applied as appropriate:

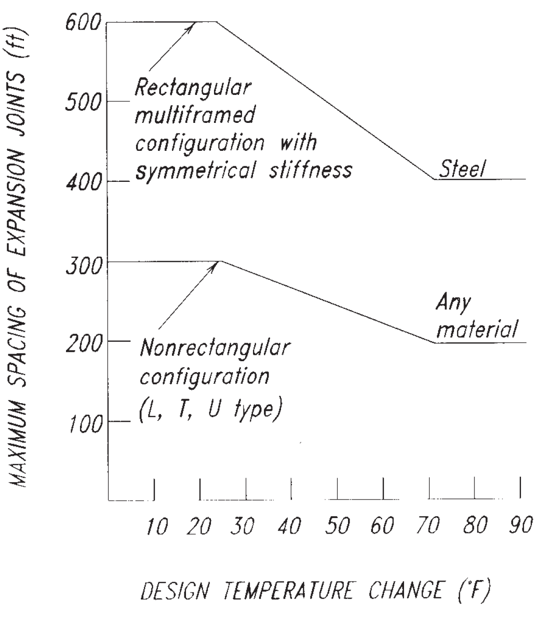


Fig. 2-6. Recommended maximum expansion-joint spacing.

1. If the building will be heated only and will have pinned column bases, use the maximum spacing as specified.
2. If the building will be air-conditioned as well as heated, increase the maximum spacing by 15% provided the environmental control system will run continuously.
3. If the building will be unheated, decrease the maximum spacing by 33%.
4. If the building will have fixed column bases, decrease the maximum spacing by 15%.
5. If the building will have substantially greater stiffness against lateral displacement in one of the plan dimensions, decrease the maximum spacing by 25%.

When more than one of these design conditions prevail in a building, the percentile factor to be applied is the algebraic sum of the adjustment factors of all the various applicable conditions. Most building codes include restrictions on location and maximum spacing of fire walls, which often become default locations for expansion joints.

The most effective expansion joint is a double line of columns that provides a complete and positive separation. Alternatively, low-friction sliding elements can be used. Such systems, however, are seldom totally friction-free and will induce some level of inherent restraint to movement.

Elevated-Temperature Service

For applications involving short-duration loading at elevated temperature, the variations in yield strength, tensile strength, and modulus of elasticity are given in AISC Design Guide 19, *Fire Resistance of Structural Steel Framing* (Ruddy et al., 2003). For applications involving long-duration loading at elevated temperatures, the effects of creep must also be considered. For further information, see Brockenbrough and Merritt (1999; pp. 1.20–1.22).

FATIGUE AND FRACTURE CONTROL

Avoiding Brittle Fracture

By definition, brittle fracture occurs by cleavage at a stress level below the yield strength. Generally, a brittle fracture can occur when there is a sufficiently adverse combination of tensile stress, temperature, strain rate and geometrical discontinuity (notch). The exact combination of these conditions and other factors that will cause brittle fracture cannot be readily calculated. Consequently, the best guide in selecting steel material that is appropriate for a given application is experience.

The steels listed in AISC *Specification* Section A3.1a, Section A3.1c and Section A3.1d have been successfully used in a great number of applications, including buildings, bridges, transmission towers and transportation equipment, even at the lowest atmospheric temperatures encountered in the United States. Nonetheless, it is desirable to minimize the conditions that tend to cause brittle fracture: triaxial state-of-stress, increased strain rate, strain aging, stress risers, welding residual stresses, areas of reduced notch toughness, and low-temperature service.

1. Triaxial state-of-stress: While shear stresses are always present in a uniaxial or biaxial state-of-stress, the maximum shear stress approaches zero as the principal stresses approach a common value in a triaxial state-of-stress. A triaxial state-of-stress can also result from uniaxial loading when notches or geometrical discontinuities are present. A triaxial state-of-stress will cause the yield stress of the material to increase above its

nominal value, resulting in brittle fracture by cleavage, rather than ductile shear deformations. As a result, in the absence of critical-size notches, the maximum stress is limited by the yield stress of the nearby unaffected material. Triaxial stress conditions should be avoided, when possible.

2. Increased strain rate: Gravity loads, wind loads and seismic loads have essentially similar strain rates. Impact loads, such as those associated with heavy cranes, and blast loads normally have increased strain rates, which tend to increase the possibility of brittle fracture. Note, however, that a rapid strain rate or impact load is not a required condition for the occurrence of brittle fracture.
3. Strain aging: Cold working of steel and the strain aging that normally results generally increases the likelihood of brittle fracture, usually due to a reduction in ductility and notch toughness. The effects of cold work and strain aging can be minimized by selecting a generous forming radius to eliminate or minimize strain hardening.
4. Stress risers: Fabrication operations, such as flame cutting and welding, may induce geometric conditions or discontinuities that are crack-like in nature, creating stress risers. Intersecting welds from multiple directions should be avoided with properly sized weld access holes to minimize the interaction of these various stress fields. Such conditions should be avoided, when possible, or removed or repaired when they occur.
5. Welding residual stresses: In the as-welded condition, residual stresses near the yield strength of the material will be present in any weldment. Residual stresses and the possible accompanying distortions can be minimized through controlled welding procedures and fabrication methods, including the proper positioning of the components of the joint prior to welding, the selection of welding sequences that will minimize distortions, the use of preheat as appropriate, the deposition of a minimum volume of weld metal with a minimum number of passes for the design condition, and proper control of interpass temperatures and cooling rates. In fracture-sensitive applications, notch-toughness should be specified for both the base metal and the filler metal.
6. Areas of reduced notch toughness: Such areas can be found in the core areas of heavy shapes and plates and the *k*-area of rotary-straightened W-shapes. Accordingly, AISC *Specification* Sections A3.1c and Section A3.1d include special requirements for material notch toughness.
7. Low-temperature service: While steel yield strength, tensile strength, modulus of elasticity, and fatigue strength increase as temperature decreases, ductility and toughness decrease. Furthermore, there is a temperature below which steel subjected to tensile stress may fracture by cleavage, with little or no plastic deformation, rather than by shear, which is usually preceded by considerable inelastic deformation. Note that cleavage and shear are used in the metallurgical sense to denote different fracture mechanisms.

When notch-toughness is important, Charpy V-notch testing can be specified to ensure a certain level of energy absorption at a given temperature, such as 15 ft-lb at 70 °F. Note that the appropriate test temperature may be higher than the lowest operating temperature depending upon the rate of loading. Although it is primarily intended for bridge-related applications, the information in ASTM A709 Section S83 (including Tables S1.1, S1.2 and S1.3) may be useful in determining the proper level of notch toughness that should be specified.

In many cases, weld metal notch toughness exceeds that of the base metal. Filler metals can be selected to meet a desired minimum notch-toughness value. For each welding process, electrodes exist that have no specified notch toughness requirements. Such electrodes should not be assumed to possess any minimum notch-toughness value. When notch toughness is necessary for a given application, the desired value or an appropriate electrode should be specified in the contract documents.

For further information, refer to Fisher et al. (1998), Barsom and Rolfe (1999), and Rolfe (1977).

Avoiding Lamellar Tearing

Although lamellar tearing is less common today, the restraint against solidified weld deposit contraction inherent in some joint configurations can impose a tensile strain high enough to cause separation or tearing on planes parallel to the rolled surface of the element being joined. The incidence of this phenomenon can be reduced or eliminated through greater understanding by designers, detailers and fabricators of the inherent directionality of rolled steel, the importance of strains associated with solidified weld deposit contraction in the presence of high restraint (rather than externally applied design forces), and the need to adopt appropriate joint and welding details and procedures with proper weld metal for through-thickness connections.

Dexter and Melendrez (2000) demonstrate that W-shapes are not susceptible to lamellar tearing or other through-thickness failures when welded tee joints are made to the flanges at locations away from member ends. When needed for other conditions, special production practices can be specified for steel plates to assist in reducing the incidence of lamellar tearing by enhancing through-thickness ductility. For further information, refer to ASTM A770. However, it must be recognized that it is more important and effective to properly design, detail and fabricate to avoid highly restrained joints. AISC (1973) provides guidelines that minimize potential problems.

WIND AND SEISMIC DESIGN

In general, nearly all building design and construction can be classified into one of two categories: wind and low-seismic applications, and high-seismic applications. For additional discussion regarding seismic design and the applicability of the AISC *Seismic Provisions*, see the Scope statement at the front of this manual.

Wind and Low-Seismic Applications

Wind and low-seismic applications are those in which the AISC *Seismic Provisions* are not applicable. Such buildings are designed to meet the provisions in the AISC *Specification* based upon the code-specified forces distributed throughout the framing assuming a nominally elastic structural response. The resulting systems have normal levels of ductility. It is important to note that the applicable building code includes seismic design requirements even if the AISC *Seismic Provisions* are not applicable. See the AISC *Seismic Design Manual* for additional discussion.

High-Seismic Applications

High-seismic applications are those in which the building is designed to meet the provisions in both the AISC *Seismic Provisions* and the AISC *Specification*. Note that it does not matter if wind or earthquake controls in this case. High-seismic design and construction will generally cost more than wind and low-seismic design and construction, as the resulting systems are designed to have high levels of ductility.

High-seismic lateral framing systems are configured to be capable of withstanding strong ground motions as they undergo controlled ductile deformations to dissipate energy. Consider the following three examples:

1. Special Concentrically Braced Frames (SCBF)—SCBF are generally configured so that any inelasticity will occur by tension yielding and/or compression buckling in the braces. The connections of the braces to the columns and beams and between the columns and beams themselves must then be proportioned to remain nominally elastic as they undergo these deformations.
2. Eccentrically Braced Frames (EBF)—EBF are generally configured so that any inelasticity will occur by shear yielding and/or flexural yielding in the link. The beam outside the link, connections, braces and columns must then be proportioned to remain nominally elastic as they undergo these deformations.
3. Special Moment Frames (SMF)—SMF are generally configured so that any inelasticity will occur by flexural yielding in the girders near, but away from, the connection of the girders to the columns. The connections of the girders to the columns and the columns themselves must then be proportioned to remain nominally elastic as they undergo these deformations. Intermediate moment frames (IMF) and ordinary moment frames (OMF) are also configured to provide improved seismic performance, although successively lower than that for SMF.

The code-specified base accelerations used to calculate the seismic forces are not necessarily maximums, but rather, they represent the intensity of ground motions that have been selected by the code-writing authorities as reasonable for design purposes. Accordingly, the requirements in both the AISC *Seismic Provisions* and the AISC *Specification* must be met so that the resulting frames can then undergo controlled deformations in a ductile, well-distributed manner.

The design provisions for high-seismic systems are also intended to result in distributed deformations throughout the frame, rather than the formation of story mechanisms, so as to increase the level of available energy dissipation and corresponding level of ground motion that can be withstood.

The member sizes in high-seismic frames will be larger than those in wind and low-seismic frames. The connections will also be much more robust so they can transmit the member-strength-driven force demands. Net sections will often require special attention so as to avoid having fracture limit states control. Special material requirements, design considerations and construction practices must be followed. For further information on the design and construction of high-seismic systems, see the AISC *Seismic Provisions*, which are available at **www.aisc.org**.

Table 2-2
Summary Comparison of Methods for Stability Analysis and Design

	Direct Analysis Method	Effective Length Method	First-Order Analysis Method
Limitations on Use[a]	None	$\Delta_{2nd}/\Delta_{1st} \le 1.5$	$\Delta_{2nd}/\Delta_{1st} \le 1.5$ $\alpha P_r/P_y \le 0.5$
Analysis Type	Second-order elastic[b]		First-order elastic
Geometry of Structure	All three methods use the undeformed geometry in the analysis.		
Minimum or Additional Lateral Loads Required in the Analysis	Minimum;[c] 0.2% of the story gravity load	Minimum; 0.2% of the story gravity load	Additive; at least 0.42% of the story gravity load
Member Stiffnesses Used in the Analysis	Reduced *EA* and *EI*	Nominal *EA* and *EI*	
Design of Columns	$K = 1$ for all frames	$K = 1$ for braced frames. For moment frames, determine K from sidesway buckling analysis[d]	$K = 1$ for all frames[e]
Specification Reference for Method	Chapter C	Appendix Section 7.2	Appendix Section 7.3

[a] $\Delta_{2nd}/\Delta_{1st}$ is the ratio of second-order drift to first-order drift, which can be taken to be equal to B_2 calculated per Appendix 8. $\Delta_{2nd}/\Delta_{1st}$ is determined using LRFD load combinations or a multiple of 1.6 times ASD load combinations.
[b] Either a general second-order analysis method or second-order analysis by amplified first-order analysis (the "B_1-B_2 method" described in Appendix 8) can be used.
[c] This notional load is additive if $\Delta_{2nd}/\Delta_{1st} > 1.5$.
[d] $K = 1$ is permitted for moment frames when $\Delta_{2nd}/\Delta_{1st} \le 1.1$.
[e] An additional amplification for member curvature effects is required for columns in moment frames.

Table 2-3
AISI Standard Nomenclature for Flat-Rolled Carbon Steel

Thickness, in.	Width, in.: To 3½ incl.	Over 3½ To 6	Over 6 To 8	Over 8 To 12	Over 12 To 48	Over 48
0.2300 & thicker	Bar	Bar	Bar	Plate	Plate	Plate
0.2299 to 0.2031	Bar	Bar	Strip	Strip	Sheet	Plate
0.2030 to 0.1800	Strip	Strip	Strip	Strip	Sheet	Plate
0.1799 to 0.0449	Strip	Strip	Strip	Strip	Sheet	Sheet
0.0448 to 0.0344	Strip	Strip				
0.0343 to 0.0255	Strip		Hot-rolled sheet and strip not generally produced in these widths and thicknesses			
0.0254 & thinner

■ = Preferred material specification
▒ = Other applicable material specification, the availability of which should be confirmed prior to specification
□ = Material specification does not apply

[a] Minimum unless a range is shown.
[b] For shapes over 426 lb/ft, only the minimum of 58 ksi applies.
[c] For shapes with a flange thickness less than or equal to 1½ in. only. To improve weldability, a maximum carbon equivalent can be specified (per ASTM Supplementary Requirement S78). If desired, maximum tensile stress of 90 ksi can be specified (per ASTM Supplementary Requirement S79).
[d] If desired, maximum tensile stress of 70 ksi can be specified (per ASTM Supplementary Requirement S81).
[e] For shapes with a flange thickness less than or equal to 2 in. only.
[f] ASTM A618 can also be specified as corrosion-resistant; see ASTM A618.
[g] Minimum applies for walls nominally ¾-in. thick and under. For wall thicknesses over ¾ in., $F_y = 46$ ksi and $F_u = 67$ ksi.
[h] If desired, maximum yield stress of 65 ksi and maximum yield-to-tensile strength ratio of 0.85 can be specified (per ASTM Supplementary Requirement S75).
[i] A maximum yield-to-tensile strength ratio of 0.85 and carbon equivalent formula are included as mandatory in ASTM A992.
[j] For shapes with a flange thickness greater than 2 in. only.
[k] For shapes with a flange thickness greater than 1½ in. and less than or equal to 2 in. only.
[l] For shapes with a flange thickness less than or equal to 1½ in. only.

□ = Material specification does not apply

— Indicates that a value is not specified in the material specification.
[a] Minimum unless a range is shown or maximum (max.) is indicated.
[b] Special washer requirements may apply per RCSC *Specification* Table 6.1 for some steel-to-steel bolting applications and per Part 14 for anchor-rod applications.
[c] See AISC *Specification* Section J3.1 for limitations on use of ASTM A449 bolts.
[d] When atmospheric corrosion resistance is desired, Type 3 can be specified.
[e] For anchor rods with temperature and corrosion resistance characteristics.

Table 2-7
Metal Fastener Compatibility to Resist Corrosion

Base Metal \ Fastener Metal	Zinc and Galvanized Steel	Aluminum and Aluminum Alloys	Steel and Cast Iron	Brasses, Copper, Bronzes, Monel	Martensitic Stainless Steel (Type 410)	Austenitic Stainless Steel (Type 302/304, 303, 305)
Zinc and Galvanized Steel	A	B	B	C	C	C
Aluminum and Aluminum Alloys	A	A	B	C	Not Recommended	B
Steel and Cast Iron	A, D	A	A	C	C	B
Terne (Lead-Tin) Plated Steel Sheets	A, D, E	A, E	A, E	C	C	B
Brasses, Copper, Bronzes, Monel	A, D, E	A, E	A, E	A	A	B
Ferritic Stainless Steel (Type 430)	A, D, E	A, E	A, E	A	A	A
Austenitic Stainless Steel (Type 302/304)	A, D, E	A, E	A, E	A, E	A	A

KEY

A. The corrosion of the base metal is not increased by the fastener.
B. The corrosion of the base metal is marginally increased by the fastener.
C. The corrosion of the base metal may be markedly increased by the fastener material.
D. The plating on the fastener is rapidly consumed, leaving the bare fastener metal.
E. The corrosion of the fastener is increased by the base metal.

NOTE: Surface treatment and environment can change activity. For a more thorough understanding of metal corrosion in construction materials, please consult a full listing of the galvanic series of metals and alloys.

Note: Reprinted from the Specialty Steel Industry of North America *Stainless Steel Fasteners Designer's Handbook*.

Table 2-8
Summary of Surface Preparation Specifications

SSPC Specification No.	Title	Description
SP1	Solvent Cleaning	Removal of oil, grease, dirt, soil, salts and contaminants by cleaning with solvent, vapor, alkali, emulson or steam.
SP2	Hand-Tool Cleaning	Removal of all loose rust, loose mill scale and loose paint to degree specified, by hand-chipping, scraping, sanding and wire brushing.
SP3	Power-Tool Cleaning	Removal of all loose rust, loose mill scale and loose paint to degree specified, by power-tool chipping, descaling, sanding, wire brushing, and grinding.
SP5/NACE No.1	Metal Blast Cleaning	Removal of all visible rust, mill scale, paint and foreign matter by blast-cleaning by wheel or nozzle (dry or wet) using sand, grit or shot. (For very corrosive atmospheres where high cost of cleaning is warranted.)
SP6/NACE No.3	Commercial Blast-Cleaning	Blast-cleaning until at least two-thirds of the surface area is free of all visible residues. (For conditions where thoroughly cleaned surface is required.)
SP7/NACE No. 4	Brush-Off Blast-Cleaning	Blast-cleaning of all except tightly adhering residues of mill scale, rust and coatings, exposing numerous evenly distributed flecks of underlying metal.
SP8	Pickling	Complete removal of rust and mill scale by acid-pickling, duplex-pickling or electrolytic pickling.
SP10/NACE No.2	Near-White Blast-Cleaning	Blast-cleaning to nearly white metal cleanliness, until at least 95% of the surface area is free of all visible residues. (For high humidity, chemical atmosphere, marine or other corrosive environments.)
SP11	Power-Tool Cleaning to Bare Metal	Complete removal of all rust, scale and paint by power tools, with resultant surface profile.

PART 3

DESIGN OF FLEXURAL MEMBERS

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of flexural members subject to uniaxial flexure without axial forces or torsion. For the design of members subject to biaxial flexure and/or flexure in combination with axial tension or compression and/or torsion, see Part 6.

SECTION PROPERTIES AND AREAS

For Flexure

Flexural design properties are based upon the full cross section with no reduction for bolt holes when the limitations in AISC *Specification* Section F13.1(a) are satisfied. Otherwise, the flexural design properties are based upon a flexural rupture check given in AISC *Specification* Section F13.1(b).

For Shear

For shear, the area is determined per AISC *Specification* Chapter G.

FLEXURAL STRENGTH

The nominal flexural strength of W-shapes is illustrated as a function of the unbraced length, L_b, in Figure 3-1. The available strength is determined as ϕM_n or M_n/Ω, which must equal or exceed the required strength (bending moment), M_u or M_a, respectively. The available flexural strength, ϕM_n or M_n/Ω, is determined per AISC *Specification* Chapter F. Table User Note F1.1 outlines the sections of Chapter F and the corresponding limit states applicable to each member type.

Braced, Compact Flexural Members

When flexural members are braced ($L_b \le L_p$) and compact ($\lambda \le \lambda_p$), yielding must be considered in the nominal moment strength of the member, in accordance with the requirements of AISC *Specification* Chapter F.

Unbraced Flexural Members

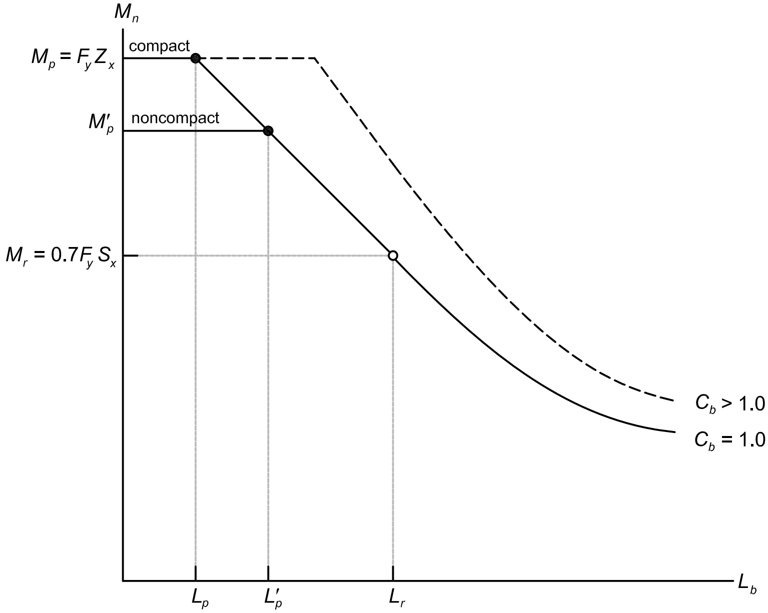
When flexural members are unbraced ($L_b > L_p$), have flange width-to-thickness ratios such that $\lambda > \lambda_p$, or have web width-to-thickness ratios such that $\lambda > \lambda_p$, lateral-torsional and elastic buckling effects must be considered in the calculation of the nominal moment strength of the member.

Noncompact or Slender Cross Sections

For flexural members that have width-to-thickness ratios such that $\lambda > \lambda_p$, local buckling must be considered in the calculation of the nominal moment strength of the member.

Available Flexural Strength for Weak-Axis Bending

The design of flexural members subject to weak-axis bending is similar to that for strong-axis bending, except that lateral-torsional buckling and web local buckling do not apply. See AISC *Specification* Section F6.



$$L_p = 1.76 r_y \sqrt{\frac{E}{F_y}} \qquad \text{(\textit{Spec}. Eq. F2-5)}$$

$$L_r = 1.95 r_{ts} \frac{E}{0.7F_y} \sqrt{\frac{Jc}{S_x h_o} + \sqrt{\left(\frac{Jc}{S_x h_o}\right)^2 + 6.76\left(\frac{0.7F_y}{E}\right)^2}} \qquad \text{(\textit{Spec}. Eq. F2-6)}$$

$$M_r = 0.7F_y S_x \qquad \text{(3-1)}$$

For cross sections with noncompact flanges:

$$M'_p = M_n = M_p - \left(M_p - 0.7F_y S_x\right)\left(\frac{\lambda - \lambda_{pf}}{\lambda_{rf} - \lambda_{pf}}\right) \qquad \text{(from \textit{Spec}. Eq. F3-1)}$$

$$L'_p = L_p + \left(L_r - L_p\right)\frac{\left(M_p - M'_p\right)}{\left(M_p - M_r\right)} \qquad \text{(3-2)}$$

Fig. 3-1. General available flexural strength of beams.

LOCAL BUCKLING

Determining the Width-to-Thickness Ratios of the Cross Section

Flexural members are classified for flexure on the basis of the width-to-thickness ratios of the various elements of the cross section. The width-to-thickness ratio, λ, is determined for each element of the cross section per AISC *Specification* Section B4.1.

Classification of Cross Sections

Cross sections are classified as follows:

- Flexural members are compact (the plastic moment can be reached without local buckling) when λ is equal to or less than λ_p and the flange(s) are continuously connected to the web(s).
- Flexural members are noncompact (local buckling will occur, but only after initial yielding) when λ exceeds λ_p but is equal to or less than λ_r.
- Flexural members are slender-element cross sections (local buckling will occur prior to yielding) when λ exceeds λ_r.

The values of λ_p and λ_r are determined per AISC *Specification* Section B4.1.

LATERAL-TORSIONAL BUCKLING

Classification of Spans for Flexure

Flexural members bent about their strong axis are classified on the basis of the length, L_b, between braced points. Braced points are points at which support resistance against lateral-torsional buckling is provided per AISC *Specification* Appendix 6, Section 6.3. Classifications are determined as follows:

- If $L_b \le L_p$, flexural member is not subject to lateral-torsional buckling.
- If $L_p < L_b \le L_r$, flexural member is subject to inelastic lateral-torsional buckling.
- If $L_b > L_r$, flexural member is subject to elastic lateral-torsional buckling.

The values of L_p and L_r are determined per AISC *Specification* Chapter F. These values are presented in Tables 3-2, 3-6, 3-7, 3-8, 3-9, 3-10 and 3-11. Note that for cross sections with noncompact flanges, the value given for L_p in these tables is L_p' as given in Equation 3-2 of Figure 3-1. In Tables 3-10 and 3-11, L_p is defined by • and L_r by ∘.

Lateral-torsional buckling does not apply to flexural members bent about their weak axis or HSS bent about either axis, per AISC *Specification* Sections F6, F7 and F8.

Consideration of Moment Gradient

When $L_b > L_p$, the moment gradient between braced points can be considered in the determination of the available strength using the lateral-torsional buckling modification factor, C_b, herein referred to as the LTB modification factor. In the case of a uniform moment between braced points causing single-curvature of the member, $C_b = 1.0$. This represents the worst case and C_b can be conservatively taken equal to 1.0 for use with the maximum moment between braced points in most designs. See AISC *Specification* Commentary

Section F1 for further discussion. A nonuniform moment gradient between braced points can be considered using C_b calculated as given in AISC *Specification* Equation F1-1. Exceptions are provided as follows:

1. As an alternative, when the moment diagram between braced points is a straight line, C_b can be calculated as given in AISC *Specification* Commentary Equation C-F1-1.
2. For cantilevers or overhangs where the free end is unbraced, C_b = 1.0 per AISC *Specification* Section F1.
3. For tees with the stem in compression, C_b = 1.0 as recommended in AISC *Specification* Commentary Section F9.

AVAILABLE SHEAR STRENGTH

For flexural members, the available shear strength, ϕV_n or V_n/Ω, which must equal or exceed the required strength, V_u or V_a, respectively, is determined in accordance with AISC *Specification* Chapter G. Values of ϕV_n and V_n/Ω can be found in Tables 3-2, 3-6, 3-7, 3-8 and 3-9.

STEEL W-SHAPE BEAMS WITH COMPOSITE SLABS

The following pertains to W-shapes with composite concrete slabs in regions of positive moment. For composite flexural members in regions of negative moment, see AISC *Specification* Chapter I. For further information on composite design and construction, see Viest et al. (1997).

Concrete Slab Effective Width

The effective width of a concrete slab acting compositely with a steel beam is determined per AISC *Specification* Section I3.1a.

Steel Anchors

Material, placement and spacing requirements for steel anchors are given in AISC *Specification* Chapter I. The nominal shear strength, Q_n, of one steel headed stud anchor is determined per AISC *Specification* Section I8.2a and is tabulated for common design conditions in Table 3-21. The horizontal shear strength, V_r', at the steel-concrete interface will be the least of the concrete crushing strength, steel tensile yield strength, or the shear strength of the steel anchors. Table 3-21 considers only the limit state of shear strength of a steel headed stud anchor.

Available Flexural Strength for Positive Moment

The available flexural strength of a composite beam subject to positive moment is determined per AISC *Specification* Section I3.2a assuming a uniform compressive stress of $0.85f_c'$ and zero tensile strength in the concrete, and a uniform stress of F_y in the tension area (and compression area, if any) of the steel section. The position of the plastic neutral axis (PNA) can then be determined by static equilibrium.

Per AISC *Specification* Section I3.2d, enough steel anchors must be provided between a point of maximum moment and the nearest point of zero moment to transfer the total horizontal shear force, V_r', between the steel beam and concrete slab, where V_r' is determined per

AISC *Specification* Section I3.2d(1). For partial composite design, the horizontal shear strength, V_r', controls the available flexural strength of the composite flexural member.

Shored and Unshored Construction

The available flexural strength is identical for both shored and unshored construction. In unshored construction, issues such as lateral support during construction and construction-load deflection may require consideration.

Available Shear Strength

Per AISC *Specification* Section I4, the available shear strength for composite beams is determined as illustrated previously for steel beams.

OTHER SPECIFICATION REQUIREMENTS AND DESIGN CONSIDERATIONS

The following other specification requirements and design considerations apply to the design of flexural members.

Special Requirements for Heavy Shapes and Plates

For beams with complete-joint-penetration groove welded joints and made from heavy shapes with a flange thickness exceeding 2 in., see AISC *Specification* Sections A3.1c.

For built-up sections consisting of plates with a thickness exceeding 2 in., see Section A3.1d.

Serviceability

Serviceability requirements, per AISC *Specification* Chapter L, should be appropriate for the application. This includes an appropriate limit on the deflection of the flexural member and the vibration characteristics of the system of which the flexural member is a part. See also AISC Design Guide 3, *Serviceability Design Considerations for Steel Buildings* (West et al., 2003), AISC Design Guide 5, *Low- and Medium-Rise Steel Buildings* (Allison, 1991) and AISC Design Guide 11, *Floor Vibrations Due to Human Activity* (Murray et al., 1997).

The maximum vertical deflection, Δ, can be calculated using the equations given in Tables 3-22 and 3-23. Alternatively, for common cases of simple-span beams and I-shaped members and channels, the following equation can be used:

$$\Delta = ML^2/(C_1 I_x) \tag{3-3}$$

where

M = maximum service-load moment, kip-ft

L = span length, ft

I_x = moment of inertia, in.^{4}

C_1 = loading constant (see Figure 3-2) which includes the numerical constants appropriate for the given loading pattern, E (29,000 ksi), and a ft-to-in. conversion factor of 1,728 in.^{3}/ft^3.

DESIGN TABLE DISCUSSION

Flexural Design Tables

Table 3-1. Values of C_b for Simply Supported Beams

Values of the LTB modification factor, C_b, are given for various loading conditions on simple-span beams in Table 3-1.

W-Shape Selection Tables

Table 3-2. W-Shapes—Selection by Z_x

W-shapes are sorted in descending order by strong-axis flexural strength and then grouped in ascending order by weight with the lightest W-shape in each range in bold. Strong-axis available strengths in flexure and shear are given for W-shapes with F_y = 50 ksi (ASTM A992). C_b is taken as unity.

For compact W-shapes, when $L_b \le L_p$, the strong-axis available flexural strength, $\phi_b M_{px}$ or M_{px}/Ω_b, can be determined using the tabulated strength values. When $L_p < L_b \le L_r$, linearly interpolate between the available strength at L_p and the available strength at L_r as follows:

LRFD	ASD
$\phi_b M_n = C_b\left[\phi_b M_{px} - \phi_b BF(L_b - L_p)\right] \le \phi_b M_{px}$ (3-4a)	$\dfrac{M_n}{\Omega_b} = C_b\left[\dfrac{M_{px}}{\Omega_b} - \dfrac{BF}{\Omega_b}(L_b - L_p)\right] \le \dfrac{M_{px}}{\Omega_b}$ (3-4b)

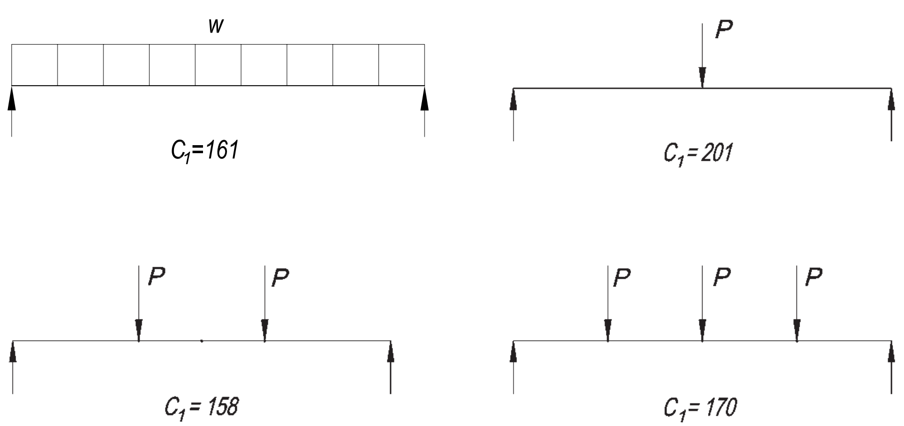


Fig. 3-2. Loading constants for use in determining simple beam deflections.

where

$$BF = \frac{\left(M_{px} - M_{rx}\right)}{\left(L_r - L_p\right)} \tag{3-5}$$

L_p = for compact sections, see Figure 3-1, AISC *Specification* Equation F2-5

= for noncompact sections, $L_p = L'_p$, see Figure 3-1, Equation 3-2

L_r = see Figure 3-1, AISC *Specification* Equation F2-6

$M_{px} = F_y Z_x$ for compact sections (*Spec.* Eq. F2-1)

$= M'_p$ as given in Figure 3-1, AISC *Specification* Equation F3-1, for noncompact sections

$M_{rx} = M_r$, see Figure 3-1

$\phi_b = 0.90$

$\Omega_b = 1.67$

When $L_b > L_r$, see Table 3-10.

The strong-axis available shear strength, $\phi_v V_{nx}$ or V_{nx}/Ω_v, can be determined using the tabulated value.

Table 3-3. W-Shapes—Selection by I_x

W-shapes are sorted in descending order by strong-axis moment of inertia, I_x, and then grouped in ascending order by weight with the lightest W-shape in each range in bold.

Table 3-4. W-Shapes—Selection by Z_y

W-shapes are sorted in descending order by weak-axis flexural strength and then grouped in ascending order by weight with the lightest W-shape in each range in bold. Weak-axis available strengths in flexure are given for W-shapes with $F_y = 50$ ksi (ASTM A992). C_b is taken as unity.

For noncompact W-shapes, the tabulated values of M_{ny}/Ω_b and $\phi_b M_{ny}$ have been adjusted to account for the noncompactness.

The weak-axis available shear strength must be checked independently.

Table 3-5. W-Shapes—Selection by I_y

W-shapes are sorted in descending order by weak-axis moment of inertia, I_y, and then grouped in ascending order by weight with the lightest W-shape in each range in bold.

Maximum Total Uniform Load Tables

Table 3-6. W-Shapes—Maximum Total Uniform Load

Maximum total uniform loads on braced ($L_b \le L_p$) simple-span beams bent about the strong axis are given for W-shapes with $F_y = 50$ ksi (ASTM A992). The uniform load constant, $\phi_b W_c$ or W_c/Ω_b (kip-ft), divided by the span length, L (ft), provides the maximum total uniform load (kips) for a braced simple-span beam bent about the strong axis. This is based on the available flexural strength as discussed for Table 3-2.

The strong-axis available shear strength, $\phi_v V_n$ or V_n/Ω_v, can be determined using the tabulated value. Above the heavy horizontal line in the tables, the maximum total uniform load is limited by the strong-axis available shear strength.

The tabulated values can also be used for braced simple-span beams with equal concentrated loads spaced as shown in Table 3-22a if the concentrated loads are first converted to an equivalent uniform load.

Table 3-7. S-Shapes—Maximum Total Uniform Load

Table 3-7 is similar to Table 3-6, except it covers S-shapes with F_y = 36 ksi (ASTM A36).

Table 3-8. C-Shapes—Maximum Total Uniform Load

Table 3-8 is similar to Table 3-6, except it covers C-shapes with F_y = 36 ksi (ASTM A36).

Table 3-9. MC-Shapes—Maximum Total Uniform Load

Table 3-9 is similar to Table 3-6, except it covers MC-shapes with F_y = 36 ksi (ASTM A36).

Plots of Available Flexural Strength vs. Unbraced Length

Table 3-10. W-Shapes—Plots of Available Moment vs. Unbraced Length

The strong-axis available flexural strength, $\phi_b M_n$ or M_n/Ω_b, is plotted as a function of the unbraced length, L_b, for W-shapes with F_y = 50 ksi (ASTM A992). The plots show the total available strength for an unbraced length, L_b. The moment demand due to all applicable load combinations on that segment may not exceed the strength shown for L_b. C_b is taken as unity.

When the plotted curve is solid, the W-shape for that curve is the lightest cross section for a given combination of available flexural strength and unbraced length. When the plotted curve is dashed, a lighter W-shape than that for the plotted curve exists. The plotted curves are arbitrarily terminated at a span-to-depth ratio of 30 in most cases.

L_p is indicated in each curve by a solid dot (•). L_r is indicated in each curve by an open dot (◦).

Table 3-11. C- and MC-Shapes—Plots of Available Moment vs. Unbraced Length

Table 3-11 is similar to Table 3-10, except it covers C- and MC-shapes with F_y = 36 ksi (ASTM A36).

Available Flexural Strength of HSS

Table 3-12. Rectangular HSS—Available Flexural Strength

The available flexural strength is tabulated for rectangular HSS with F_y = 46 ksi (ASTM A500 Grade B) as determined by AISC *Specification* Section F7. For noncompact and slender cross sections, the tabulated values of M_n/Ω_b and $\phi_b M_n$ have been adjusted to account for the noncompactness or slenderness.

Table 3-13. Square HSS—Available Flexural Strength

Table 3-13 is similar to Table 3-12, except it covers square HSS with F_y = 46 ksi (ASTM A500 Grade B).

Table 3-14. Round HSS—Available Flexural Strength

Table 3-14 is similar to Table 3-12, except it covers round HSS with F_y = 42 ksi (ASTM A500 Grade B) and the available flexural strength is determined from AISC *Specification* Section F8.

Table 3-15. Pipe—Available Flexural Strength

Table 3-15 is similar to Table 3-14, except it covers Pipe with F_y = 35 ksi (ASTM A53 Grade B).

Strength of Other Flexural Members

Tables 3-16 and 3-17. Available Shear Stress in Plate Girders

The available shear stress for plate girders is plotted as a function of a/h and h/t_w in Tables 3-16 (for F_y = 36 ksi) and 3-17 (for F_y = 50 ksi). In part a of each table, tension field action is neglected. In part b of each table, tension field action is considered.

Table 3-18. Floor Plates

The recommended maximum uniformly distributed loads are given in Table 3-18 based upon simple-span bending between supports. Table 3-18a is for deflection-controlled applications and should be used with the appropriate serviceability load combinations. The tabulated values correspond to a maximum deflection of L/100. Table 3-18b is for flexural-strength-controlled applications and should be used with LRFD or ASD load combinations. The tabulated values correspond to a maximum bending stress of 24 ksi in LRFD and 16 ksi in ASD.

Composite Beam Selection Tables

Table 3-19. Composite W-Shapes

The available flexural strength is tabulated for W-shapes with F_y = 50 ksi (ASTM A992). The values tabulated are independent of the specific concrete flange properties allowing the designer to select an appropriate combination of concrete strength and slab geometry.

The location of the plastic neutral axis (PNA) is uniquely determined by the horizontal shear force, ΣQ_n, at the interface between the steel section and the concrete slab. With the knowledge of the location of the PNA and the distance to the centroid of the concrete flange force, ΣQ_n, the available flexural strength can be computed.

Available flexural strengths are tabulated for PNA locations at the seven locations shown. Five of these PNA locations are in the beam flange. The seventh PNA location is computed at the point where ΣQ_n equals $0.25F_yA_s$, and the sixth PNA location is halfway between the location of ΣQ_n at point five and point seven. Use of beams with a PNA below location seven is discouraged.

Table 3-19 can be used to design a composite beam by entering with a required flexural strength and determining the corresponding required ΣQ_n. Alternatively, Table 3-19 can be used to check the flexural strength of a composite beam by selecting a valid value of ΣQ_n, using Table 3-21. With the effective width of the concrete flange, b, determined per AISC *Specification* Section I3.1a, the appropriate value of the distance from concrete flange force to beam top flange, $Y2$, can be determined as

$$Y2 = Y_{con} - \frac{a}{2} \tag{3-6}$$

where

Y_{con} = distance from top of steel beam to top of concrete, in.

$$a = \frac{\Sigma Q_n}{0.85 f'_c b} \tag{3-7}$$

and the available flexural strength, $\phi_b M_n$ or M_n/Ω_b, can then be determined from Table 3-19. Values for the distance from the PNA to the beam top flange, $Y1$, are also tabulated for convenience. The parameters $Y1$ and $Y2$ are illustrated in Figure 3-3. Note that the model of the steel beam used in the calculation of the available strength assumes that

A_s = cross-sectional area of the steel section, in.^{2}
A_f = flange area, in.^{2} = $b_f t_f$
A_w = web area, in.^{2} = $(d - 2k)t_w$
K_{dep} = $k - t_f$, in.
K_{area} = $(A_s - 2A_f - A_w)/2$, in.^{2}

Table 3-20. Lower-Bound Elastic Moment of Inertia

The lower-bound elastic moment of inertia of a composite beam can be used to calculate deflection. If calculated deflections using the lower-bound moment of inertia are acceptable, a more complete elastic analysis of the composite section can be avoided. The lower-bound elastic moment of inertia is based upon the area of the beam and an equivalent concrete area equal to $\Sigma Q_n/F_y$ as illustrated in Figure 3-4, where F_y = 50 ksi. The analysis includes only the horizontal shear force transferred by the steel anchors supplied. Thus, only the portion of the concrete flange used to balance ΣQ_n is included in the determination of the lower-bound moment of inertia.

The lower bound moment of inertia, therefore, is the moment of inertia of the cross section at the required strength level. This is smaller than the corresponding moment of inertia at the service load where deflection is calculated. The value for the lower bound moment of inertia can be calculated as illustrated in AISC *Specification* Commentary Section I3.2.

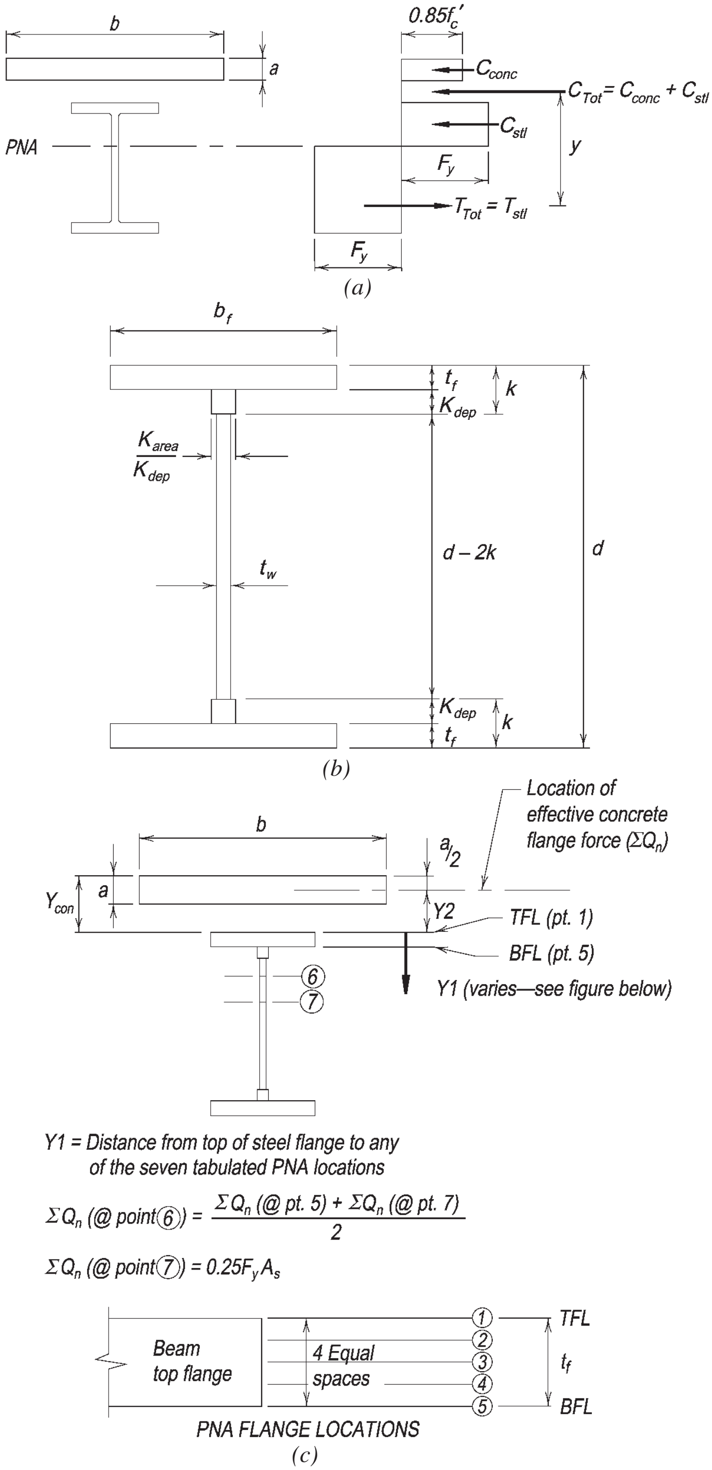

Fig. 3-3. Strength design models for composite beams.

Table 3-21. Nominal Horizontal Shear Strength for One Steel Headed Stud Anchor, Q_n

The nominal shear strength of steel headed stud anchors is given in Table 3-21, in accordance with AISC *Specification* Chapter I. Nominal horizontal shear strength values are presented based upon the position of the steel anchor, profile of the deck, and orientation of the deck relative to the steel anchor. See AISC *Specification* Commentary Figure C-I8.1.

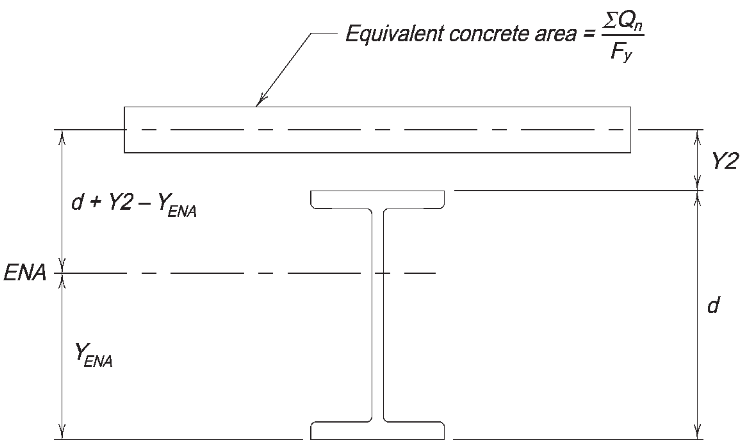

Fig. 3-4. Deflection design model for composite beams.

Beam Diagrams and Formulas

Table 3-22a. Concentrated Load Equivalents

Concentrated load equivalents are given in Table 3-22a for beams with various support conditions and loading characteristics.

Table 3-22b. Cantilevered Beams

Coefficients are provided in Table 3-22b for cantilevered beams with various support conditions and loading characteristics.

Table 3-22c. Continuous Beams

Coefficients are provided in Table 3-22c for continuous beams with various support conditions and loading characteristics.

Table 3-23. Shears, Moments and Deflections

Shears, moments and deflections are given in Table 3-23 for beams with various support conditions and loading characteristics.

$\Omega_b = 1.67$	$\phi_b = 0.90$
$\Omega_v = 1.50$	$\phi_v = 1.00$

[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi; therefore, $\phi_v = 0.90$ and $\Omega_v = 1.67$.
Note: For beams laterally unsupported, see Table 3-10.
Available strength tabulated above heavy line is limited by available shear strength.

$\Omega_b = 1.67$	$\phi_b = 0.90$
$\Omega_v = 1.50$	$\phi_v = 1.00$

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with F_y = 50 ksi; therefore, ϕ_v = 0.90 and Ω_v = 1.67.

F_y = 50 ksi

$\Omega_b = 1.67$	$\phi_b = 0.90$
$\Omega_v = 1.50$	$\phi_v = 1.00$

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.

[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with F_y = 50 ksi; therefore, ϕ_v = 0.90 and Ω_v = 1.67.

F_y = 50 ksi

ASD	LRFD
$\Omega_b = 1.67$	$\phi_b = 0.90$
$\Omega_v = 1.50$	$\phi_v = 1.00$

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with F_y = 50 ksi; therefore, $\phi_v = 0.90$ and $\Omega_v = 1.67$.

F_y = 50 ksi

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis
[b] $Y2$ = distance from top of the steel beam to concrete flange force
[c] See Figure 3-3c for PNA locations.
[d] Value in parentheses is I_x (in.[4]) of noncomposite steel shape.

F_y = 50 ksi

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis
[b] $Y2$ = distance from top of the steel beam to concrete flange force
[c] See Figure 3-3c for PNA locations.
[d] Value in parentheses is I_x (in.[4]) of noncomposite steel shape.

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis
[b] $Y2$ = distance from top of the steel beam to concrete flange force
[c] See Figure 3-3c for PNA locations.
[d] Value in parentheses is I_x (in.^{4}) of noncomposite steel shape.

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis
[b] $Y2$ = distance from top of the steel beam to concrete flange force
[c] See Figure 3-3c for PNA locations.
[d] Value in parentheses is I_x (in.^{4}) of noncomposite steel shape.

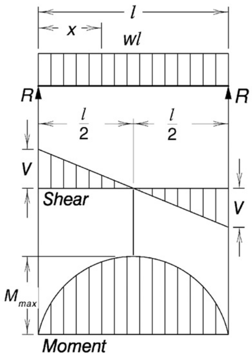
Table 3-23
Shears, Moments and Deflections

1. SIMPLE BEAM — UNIFORMLY DISTRIBUTED LOAD



Total Equiv. Uniform Load .... $= wl$

$R = V$ .... $= \dfrac{wl}{2}$

V_x .... $= w\left(\dfrac{l}{2} - x\right)$

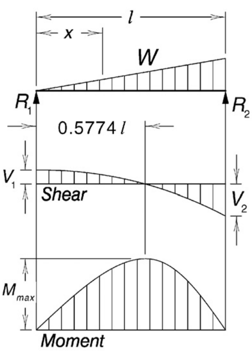
M_{max} (at center) .... $= \dfrac{wl^2}{8}$

M_x .... $= \dfrac{wx}{2}(l - x)$

Δ_{max} (at center) .... $= \dfrac{5wl^4}{384EI}$

Δ_x .... $= \dfrac{wx}{24EI}\left(l^3 - 2lx^2 + x^3\right)$

2. SIMPLE BEAM — LOAD INCREASING UNIFORMLY TO ONE END



Total Equiv. Uniform Load .... $= \dfrac{16W}{9\sqrt{3}} = 1.03W$

$R_1 = V_1$ .... $= \dfrac{W}{3}$

$R_2 = V_2 = V_{max}$ .... $= \dfrac{2W}{3}$

V_x .... $= \dfrac{W}{3} - \dfrac{Wx^2}{l^2}$

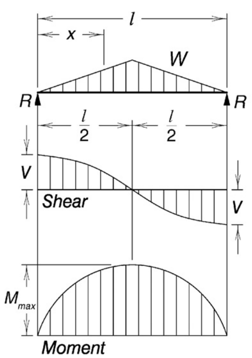
M_{max} $\left(\text{at } x = \dfrac{l}{\sqrt{3}} = 0.557\,l\right)$ .... $= \dfrac{2Wl}{9\sqrt{3}} = 0.128\,Wl$

M_x .... $= \dfrac{Wx}{3l^2}(l^2 - x^2)$

Δ_{max} $\left(\text{at } x = l\sqrt{1 - \sqrt{\dfrac{8}{15}}} = 0.519\,l\right)$ .... $= 0.0130\dfrac{Wl^3}{EI}$

Δ_x .... $= \dfrac{Wx}{180EIl^2}\left(3x^4 - 10l^2x^2 + 7l^4\right)$

3. SIMPLE BEAM — LOAD INCREASING UNIFORMLY TO CENTER



Total Equiv. Uniform Load .... $= \dfrac{4W}{3}$

$R = V$ .... $= \dfrac{W}{2}$

V_x (when $x < \dfrac{l}{2}$) .... $= \dfrac{W}{2l^2}\left(l^2 - 4x^2\right)$

M_{max} (at center) .... $= \dfrac{Wl}{6}$

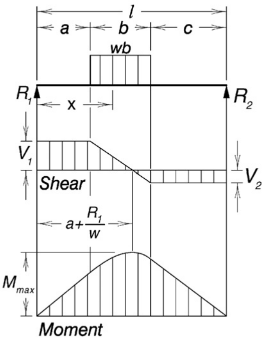
M_x (when $x < \dfrac{l}{2}$) .... $= Wx\left(\dfrac{1}{2} - \dfrac{2x^2}{3l^2}\right)$

Δ_{max} (at center) .... $= \dfrac{Wl^3}{60EI}$

Δ_x (when $x < \dfrac{l}{2}$) .... $= \dfrac{Wx}{480EIl^2}\left(5l^2 - 4x^2\right)^2$

Table 3-23 (continued)
Shears, Moments and Deflections

4. SIMPLE BEAM — UNIFORM LOAD PARTIALLY DISTRIBUTED



$R_1 = V_1$ (max. when $a < c$) .... $= \dfrac{wb}{2l}(2c + b)$

$R_2 = V_2$ (max. when $a > c$) .... $= \dfrac{wb}{2l}(2a + b)$

V_x (when $x > a$ and $< (a+b)$) .... $= R_1 - w(x - a)$

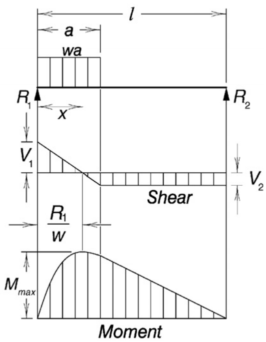
M_{max} $\left(\text{at } x = a + \dfrac{R_1}{w}\right)$ .... $= R_1\left(a + \dfrac{R_1}{2w}\right)$

M_x (when $x < a$) .... $= R_1 x$

M_x (when $x > a$ and $< (a+b)$) .... $= R_1 x - \dfrac{w}{2}(x - a)^2$

M_x (when $x > (a+b)$) .... $= R_2 (l - x)$

5. SIMPLE BEAM — UNIFORM LOAD PARTIALLY DISTRIBUTED AT ONE END



$R_1 = V_1 = V_{max}$ .... $= \dfrac{wa}{2l}(2l - a)$

$R_2 = V_2$ .... $= \dfrac{wa^2}{2l}$

V_x (when $x < a$) .... $= R_1 - wx$

M_{max} $\left(\text{at } x = \dfrac{R_1}{w}\right)$ .... $= \dfrac{R_1^2}{2w}$

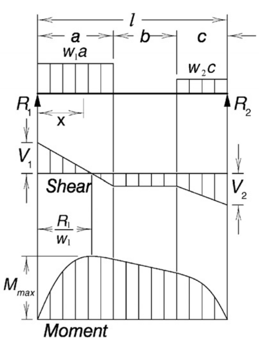
M_x (when $x < a$) .... $= R_1 x - \dfrac{wx^2}{2}$

M_x (when $x > a$) .... $= R_2 (l - x)$

Δ_x (when $x < a$) .... $= \dfrac{wx}{24EIl}\left(a^2(2l - a)^2 - 2ax^2(2l - a) + lx^3\right)$

Δ_x (when $x > a$) .... $= \dfrac{wa^2(l - x)}{24EIl}\left(4xl - 2x^2 - a^2\right)$

6. SIMPLE BEAM — UNIFORM LOAD PARTIALLY DISTRIBUTED AT EACH END



$R_1 = V_1$ .... $= \dfrac{w_1 a(2l - a) + w_2 c^2}{2l}$

$R_2 = V_2$ .... $= \dfrac{w_2 c(2l - c) + w_1 a^2}{2l}$

V_x (when $x < a$) .... $= R_1 - w_1 x$

V_x (when $a < x < (a+b)$)............ $= R_1 - w_1 a$

V_x (when $x > (a+b)$) .... $= R_2 - w_2 (l - x)$

M_{max} $\left(\text{at } x = \dfrac{R_1}{w_1}, \text{when } R_1 < w_1 a\right)$ .... $= \dfrac{R_1^2}{2w_1}$

M_{max} $\left(\text{at } x = l - \dfrac{R_2}{w_2}, \text{when } R_2 < w_2 c\right)$ $= \dfrac{R_2^2}{2w_2}$

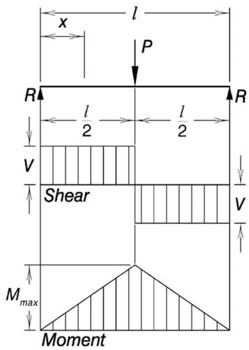
M_x (when $x < a$) .... $= R_1 x - \dfrac{w_1 x^2}{2}$

M_x (when $a < x < (a+b)$)............ $= R_1 x - \dfrac{w_1 a}{2}(2x - a)$

M_x (when $x > (a+b)$) .... $= R_2 (l - x) - \dfrac{w_2 (l - x)^2}{2}$

Table 3-23 (continued)
Shears, Moments and Deflections

7. SIMPLE BEAM — CONCENTRATED LOAD AT CENTER



Total Equiv. Uniform Load .... $= 2P$

$R = V$ .... $= \frac{P}{2}$

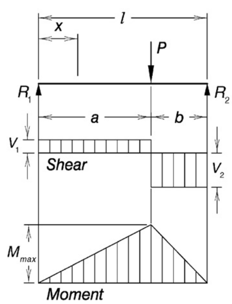
M_{max} (at point of load) .... $= \frac{Pl}{4}$

M_x (when $x < \frac{l}{2}$) .... $= \frac{Px}{2}$

Δ_{max} (at point of load) .... $= \frac{Pl^3}{48EI}$

Δ_x (when $x < \frac{l}{2}$) .... $= \frac{Px}{48EI}\left(3l^2 - 4x^2\right)$

8. SIMPLE BEAM — CONCENTRATED LOAD AT ANY POINT



Total Equiv. Uniform Load .... $= \frac{8Pab}{l^2}$

$R_1 = V_1$ ($= V_{max}$ when $a < b$) .... $= \frac{Pb}{l}$

$R_2 = V_2$ ($= V_{max}$ when $a > b$) .... $= \frac{Pa}{l}$

M_{max} (at point of load) .... $= \frac{Pab}{l}$

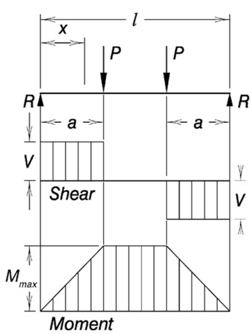
M_x (when $x < a$) .... $= \frac{Pbx}{l}$

Δ_{max} $\left(\text{at } x = \sqrt{\frac{a(a+2b)}{3}}, \text{when } a > b\right)$ .... $= \frac{Pab(a+2b)\sqrt{3a(a+2b)}}{27EIl}$

Δ_a (at point of load) .... $= \frac{Pa^2b^2}{3EIl}$

Δ_x (when $x < a$) .... $= \frac{Pbx}{6EIl}\left(l^2 - b^2 - x^2\right)$

9. SIMPLE BEAM — TWO EQUAL CONCENTRATED LOADS SYMMETRICALLY PLACED



Total Equiv. Uniform Load .... $= \frac{8Pa}{l}$

$R=V$ .... $= P$

M_{max} (between loads) .... $= Pa$

M_x (when $x < a$) .... $= Px$

Δ_{max} (at center) .... $= \frac{Pa}{24EI}\left(3l^2 - 4a^2\right)$

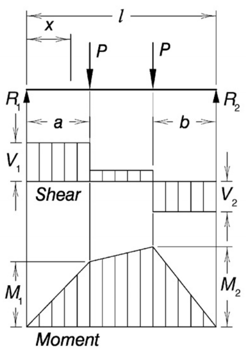
Δ_{max} (when $a = \frac{l}{3}$) .... $= \frac{23Pl^3}{648EI}$

Δ_x (when $x < a$) .... $= \frac{Px}{6EI}\left(3la - 3a^2 - x^2\right)$

Δ_x (when $a < x < (l - a)$) .... $= \frac{Pa}{6EI}\left(3lx - 3x^2 - a^2\right)$

Table 3-23 (continued)
Shears, Moments and Deflections

10. SIMPLE BEAM — TWO EQUAL CONCENTRATED LOADS UNSYMMETRICALLY PLACED



$R_1 = V_1$ ($= V_{max}$ when $a < b$) .... $= \frac{P}{l}(l - a + b)$

$R_2 = V_2$ ($= V_{max}$ when $a > b$) .... $= \frac{P}{l}(l - b + a)$

V_x (when $a < x < (l - b)$) .... $= \frac{P}{l}(b - a)$

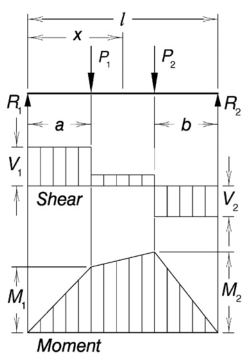
M_1 ($= M_{max}$ when $a > b$) .... $= R_1 a$

M_2 ($= M_{max}$ when $a < b$) .... $= R_2 b$

M_x (when $x < a$) .... $= R_1 x$

M_x (when $a < x < (l - b)$) .... $= R_1 x - P(x - a)$

11. SIMPLE BEAM — TWO UNEQUAL CONCENTRATED LOADS UNSYMMETRICALLY PLACED



$R_1 = V_1$ .... $= \frac{P_1(l - a) + P_2 b}{l}$

$R_2 = V_2$ .... $= \frac{P_1 a + P_2(l - b)}{l}$

V_x (when $a < x < (l - b)$) .... $= R_1 - P_1$

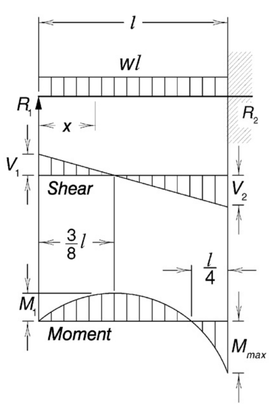
M_1 ($= M_{max}$ when $R_1 < P_1$) .... $= R_1 a$

M_2 ($= M_{max}$ when $R_2 < P_2$) .... $= R_2 b$

M_x (when $x < a$) .... $= R_1 x$

M_x (when $a < x < (l - b)$) .... $= R_1 x - P_1(x - a)$

12. BEAM FIXED AT ONE END, SUPPORTED AT OTHER — UNIFORMLY DISTRUBTED LOAD



Total Equiv. Uniform Load .... $= wl$

$R_1 = V_1$ .... $= \frac{3wl}{8}$

$R_2 = V_2 = V_{max}$ .... $= \frac{5wl}{8}$

V_x .... $= R_1 - wx$

M_{max} .... $= \frac{wl^2}{8}$

M_1 (at $x = \frac{3}{8} l$) .... $= \frac{9}{128} wl^2$

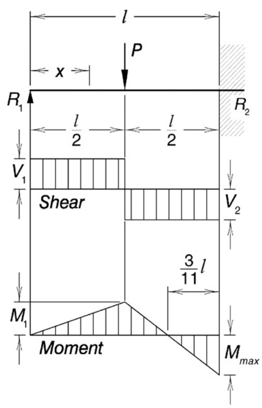
M_x .... $= R_1 x - \frac{wx^2}{2}$

Δ_{max} (at $x = \frac{l}{16}\left(1 + \sqrt{33}\right) = 0.422\, l$) .... $= \frac{wl^4}{185\, EI}$

Δ_x .... $= \frac{wx}{48\, EI}\left(l^3 - 3lx^2 + 2x^3\right)$

Table 3-23 (continued)
Shears, Moments and Deflections

13. BEAM FIXED AT ONE END, SUPPORTED AT OTHER — CONCENTRATED LOAD AT CENTER



Total Equiv. Uniform Load .... $= \frac{3P}{2}$

$R_1 = V_1$ .... $= \frac{5P}{16}$

$R_2 = V_2 = V_{max}$ .... $= \frac{11P}{16}$

M_{max} (at fixed end) .... $= \frac{3Pl}{16}$

M_1 (at point of load) .... $= \frac{5Pl}{32}$

M_x (at $x < \frac{l}{2}$) .... $= \frac{5Px}{16}$

M_x (when $x > \frac{l}{2}$) .... $= P\left(\frac{l}{2} - \frac{11x}{16}\right)$

Δ_{max} (at $x = \frac{l}{\sqrt{5}} = 0.447\,l$) .... $= \frac{Pl^3}{48EI\sqrt{5}} = 0.00932\frac{Pl^3}{EI}$

Δ_x (at point of load) .... $= \frac{7Pl^3}{768EI}$

Δ_x (at $x < \frac{l}{2}$) .... $= \frac{Px}{96EI}\left(3l^2 - 5x^2\right)$

Δ_x (at $x > \frac{l}{2}$) .... $= \frac{P}{96EI}(x-l)^2(11x-2l)$

14. BEAM FIXED AT ONE END, SUPPORTED AT THE OTHER — CONCENTRATED LOAD AT ANY POINT

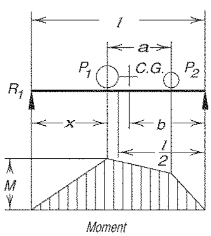
GENERAL RULES FOR SIMPLE BEAMS CARRYING MOVING CONCENTRATED LOADS



The maximum shear due to moving concentrated loads occurs at one support when one of the loads is at that support. With several moving loads, the location that will produce maximum shear must be determined by trial.

The maximum bending moment produced by moving concentrated loads occurs under one of the loads when that load is as far from one support as the center of gravity of all the moving loads on the beam is from the other support.

In the accompanying diagram, the maximum bending moment occurs under load P_1 when $x = b$. It should also be noted that this condition occurs when the center-line of the span is midway between the center of gravity of loads and the nearest concentrated load.

PART 4

DESIGN OF COMPRESSION MEMBERS

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of members subject to axial compression. For the design of members subject to eccentric compression or combined axial compression and flexure, see Part 6.

AVAILABLE COMPRESSIVE STRENGTH

The available strength of compression members, ϕP_n or P_n/Ω, which must equal or exceed the required strength, P_u or P_a, respectively, is determined according to AISC *Specification* Chapter E.

LOCAL BUCKLING

Determining the Width-to-Thickness Ratios of the Cross Section

Steel compression members are classified on the basis of the width-to-thickness ratios of the various elements of the cross section. The width-to-thickness ratio is calculated for each element of the cross section per AISC *Specification* Section B4.

Determining the Slenderness of the Cross Section

When the width-to-thickness ratios of all compression elements are less than or equal to λ_r, the cross section is nonslender, and Q, the reduction factor for slender compression elements (elastic local buckling effects), equals 1.0. When the width-to-thickness ratio of a compression element is greater than λ_r, the cross section is a slender-element cross section and Q must be included in the calculation of the available compressive strength. Q is determined per AISC *Specification* Section E7, and λ_r is determined per AISC *Specification* Section B4 and Table B4.1a.

EFFECTIVE LENGTH AND COLUMN SLENDERNESS

Columns are designed for their slenderness, KL/r, per AISC *Specification* Section E2. The effective length, KL, is equal to the effective length factor, K, multiplied by L, the physical length between braced points (see AISC *Specification* Appendix 6).

When a stability analysis is performed using the direct analysis method per AISC *Specification* Chapter C, $K = 1$.

When a stability analysis is performed using the first-order analysis method in AISC *Specification* Appendix Section 7.3, $K = 1$.

When a stability analysis is performed using the effective length method in AISC *Specification* Appendix Section 7.2, the following applies:

> $K = 1$ for columns braced at each end and whose flexural stiffnesses are not considered to contribute to lateral stability and resistance to lateral loads.
>
> $K = 1$ for all columns when the ratio of maximum second-order drift to first-order drift in all stories is less than 1.1.
>
> K shall be determined from a sidesway buckling analysis for all columns whose flexural stiffnesses are considered to contribute to lateral stability and resistance to lateral

loads. Guidance on the proper determination of the value of K is given in AISC *Specification* Commentary to Appendix Section 7.2.

As indicated in the User Note in AISC *Specification* Section E2, compression member slenderness, KL/r, should preferably be limited to a maximum of 200. Note that this recommendation does not apply to members that are primarily tension members, but subject to incidental compression under other load combinations.

Additional information is available in the SSRC *Guide to Stability Design Criteria for Metal Structures* (Ziemian, 2010).

COMPOSITE COMPRESSION MEMBERS

For the design of encased composite and filled composite compression members, see AISC *Specification* Section I2. See also AISC Design Guide 6, *Load and Resistance Factor Design of W-Shapes Encased in Concrete* (Griffis, 1992). For further information on composite design and construction, see also Viest et al. (1997).

DESIGN TABLE DISCUSSION

Steel Compression—Member Selection Tables

Table 4-1. W-Shapes in Axial Compression

Available strengths in axial compression are given for W-shapes with F_y = 50 ksi (ASTM A992). The tabulated values are given for the effective length with respect to the y-axis $(KL)_y$. However, the effective length with respect to the x-axis $(KL)_x$ must also be investigated. To determine the available strength in axial compression, the table should be entered at the larger of $(KL)_y$ and $(KL)_{y\,eq}$, where

$$\left(KL\right)_{y\,eq} = \frac{\left(KL\right)_x}{\dfrac{r_x}{r_y}} \tag{4-1}$$

Values of the ratio r_x/r_y and other properties useful in the design of W-shape compression members are listed at the bottom of Table 4-1.

Variables P_{wo}, P_{wi}, P_{wb} and P_{fb} shown in Table 4-1 can be used to determine the strength of W-shapes without stiffeners to resist concentrated forces applied normal to the face(s) of the flange(s). In these tables it is assumed that the concentrated forces act far enough away from the member ends that end effects are not considered (end effects are addressed in Chapter 9). When $P_r \le \phi R_n$ or R_n/Ω, column web stiffeners are not required. Figures 4-1, 4-2 and 4-3 illustrate the limit states and the applicable variables for each.

Web Local Yielding: The variables P_{wo} and P_{wi} can be used in the calculation of the available web local yielding strength for the column as follows:

LRFD	ASD
$\phi R_n = P_{wo} + P_{wi} l_b$ (4-2a)	$R_n/\Omega = P_{wo} + P_{wi} l_b$ (4-2b)

where

R_n = $F_{yw}t_w\,(5k + l_b) = 5F_{yw}t_wk + F_{yw}t_wl_b$, kips (AISC *Specification* Equation J10-2)
P_{wo} = $\phi 5F_{yw}t_wk$ for LRFD and $5F_{yw}t_wk/\Omega$ for ASD, kips
P_{wi} = $\phi F_{yw}t_w$ for LRFD and $F_{yw}t_w/\Omega$ for ASD, kips/in.
k = distance from outer face of flange to the web toe of fillet, in.
l_b = length of bearing, in.
t_w = thickness of web, in.
ϕ = 1.00
Ω = 1.50

Web Compression Buckling: The variable P_{wb} is the available web compression buckling strength for the column as follows:

LRFD	ASD
$\phi R_n = P_{wb}$ (4-3a)	$R_n/\Omega = P_{wb}$ (4-3b)

where

$R_n = \dfrac{24t_w^3\sqrt{EF_{yw}}}{h}$ (AISC *Specification* Equation J10-8)

$P_{wb} = \dfrac{\phi 24t_w^3\sqrt{EF_{yw}}}{h}$ for LRFD and $\dfrac{24t_w^3\sqrt{EF_{yw}}}{\Omega h}$ for ASD, kips

F_{yw} = specified minimum yield stress of the web, ksi
h = clear distance between flanges less the fillet or corner radius for rolled shapes, in.
ϕ = 0.90
Ω = 1.67

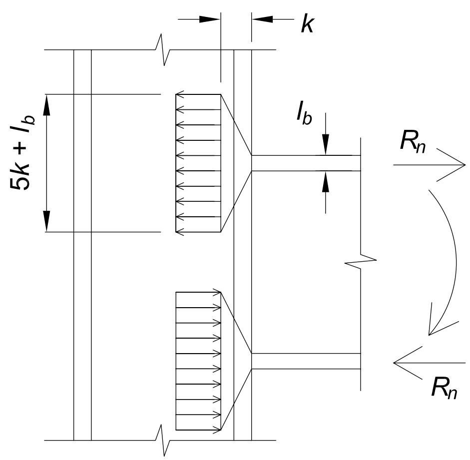


Fig. 4-1. Illustration of web local yielding limit state (AISC Specification Section J10.2).

Flange Local Bending: The variable P_{fb} is the available flange local bending strength for the column as follows:

LRFD	ASD
$\phi R_n = P_{fb}$ (4-4a)	$R_n/\Omega = P_{fb}$ (4-4b)

where

R_n = $6.25F_{yf}t_f^2$, kips (AISC *Specification* Equation J10-1)
P_{fb} = $\phi 6.25F_{yf}t_f^2$ for LRFD and $6.25F_{yf}t_f^2/\Omega$ for ASD, kips
ϕ = 0.90
Ω = 1.67

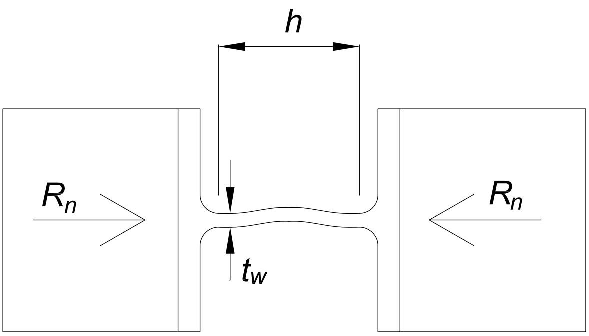

Fig. 4-2. Illustration of web compression buckling limit state (AISC Specification Section J10.5).

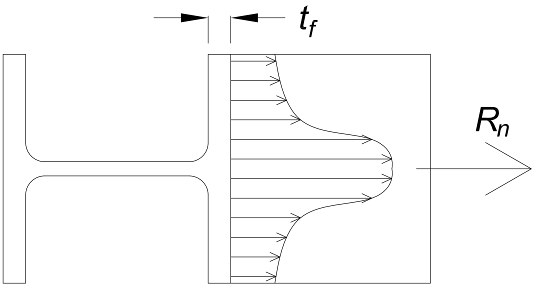

Fig. 4-3. Illustration of flange local bending limit state (AISC Specification Section J10.1).

Table 4-2. HP-Shapes in Axial Compression

Table 4-2 is similar to Table 4-1, except it covers HP-shapes with $F_y = 50$ ksi (ASTM A572 Grade 50).

Table 4-3. Rectangular HSS in Axial Compression

Available strengths in axial compression are given for rectangular HSS with $F_y = 46$ ksi (ASTM A500 Grade B). The tabulated values are given for the effective length with respect to the y-axis, $(KL)_y$. However, the effective length with respect to the x-axis $(KL)_x$ must also be investigated. To determine the available strength in axial compression, the table should be entered at the larger of $(KL)_y$ and $(KL)_{y\,eq}$, where

$$(KL)_{y\,eq} = \frac{(KL)_x}{\dfrac{r_x}{r_y}} \tag{4-1}$$

Values of the ratio r_x/r_y and other properties useful in the design of rectangular HSS compression members are listed at the bottom of Table 4-3.

Table 4-4. Square HSS in Axial Compression

Table 4-4 is similar to Table 4-3, except that it covers square HSS.

Table 4-5. Round HSS in Axial Compression

Available strengths in axial compression are given for round HSS with $F_y = 42$ ksi (ASTM A500 Grade B). To determine the available strength in axial compression, the table should be entered at KL. Other properties useful in the design of compression members are listed at the bottom of the available column strength tables.

Table 4-6. Pipe in Axial Compression

Table 4-6 is similar to Table 4-5, except it covers pipe with $F_y = 35$ ksi (ASTM A53 Grade B).

Table 4-7. WT-Shapes in Axial Compression

Available strengths in axial compression, including the limit state of flexural-torsional buckling, are given for WT-shapes with $F_y = 50$ ksi (ASTM A992). Separate tabulated values are given for the effective lengths with respect to the x- and y-axes, $(KL)_x$ and $(KL)_y$, respectively. Other properties useful in the design of WT-shape compression members are listed at the bottom of Table 4-7.

Table 4-8. Equal-Leg Double Angles in Axial Compression

Available strengths in axial compression, including the limit state of flexural-torsional buckling, are given for equal-leg double angles with $F_y = 36$ ksi (ASTM A36), assuming $^3/_8$-in. separation between the angles. These values can be used conservatively when a larger separation is provided. Alternatively, the value of $(KL)_y$ can be multiplied by the ratio of (r_y for a $^3/_8$-in. separation) to (r_y for the actual separation).

Separate tabulated values are given for the effective lengths with respect to the x- and y-axes, $(KL)_x$ and $(KL)_y$, respectively. For buckling about the x-axis, the available strength is not affected by the number of intermediate connectors. However, for buckling about the y-axis, the effects of shear deformations of the intermediate connectors must be considered. The tabulated values for $(KL)_y$ have been adjusted for the shear deformations in accordance with AISC *Specification* Equations E6-2a and E6-2b, which is applicable to welded and pretensioned bolted intermediate shear connectors. The number of intermediate connectors, n, is given in the table and the line of demarcation between the required connector values is dashed. Intermediate connectors are selected such that the available compression buckling strength about the y-axis is equal to or greater than 90% of that for compression buckling of the two angles as a unit. If fewer connectors or snug-tightened bolted intermediate connectors are used, the available strength must be recalculated per AISC *Specification* Section E6. Per AISC *Specification* Section E6.2, the slenderness of the individual components of the built-up member based upon the distance between intermediate connectors, a, must not exceed three-quarters of the controlling slenderness of the overall built-up compression member.

Other properties useful in the design of double-angle compression members are listed at the bottom of Table 4-8.

Table 4-9. LLBB Double Angles in Axial Compression

Table 4-9 is the same as Table 4-8, except that it provides available strengths in axial compression for double angles with long legs back-to-back.

Table 4-10. SLBB Double Angles in Axial Compression

Table 4-10 is the same as Table 4-8, except that it provides available strengths in axial compression for double angles with short legs back-to-back.

Table 4-11. Concentrically Loaded Single Angles in Axial Compression

Available strengths in axial compression are given for single angles, loaded through the centroid of the cross section, with $F_y = 36$ ksi (ASTM A36) based upon the effective length with respect to the z-axis, $(KL)_z$. Single angles may be assumed to be loaded through the centroid when the requirements of AISC *Specification* Section E5 are met, as in these cases the eccentricity is accounted for and the slenderness is reduced by the restraining effects of the support at both ends of the member.

Table 4-12. Eccentrically Loaded Single Angles in Axial Compression

Available strengths in axial compression are given for eccentrically loaded single angles with $F_y = 36$ ksi (ASTM A36).

The long leg of the angle is assumed to be attached to a gusset plate with a thickness of $1.5t$. The tabulated values assume a load placed at the mid-width of the long leg of the angle at a distance of $0.75t$ from the face of this leg.

Effective length, KL, is assumed to be the same on all axes (r_x, r_y, r_z and r_w). Table 4-12 considers the combined bending stresses at the heel and the tips of the angle (points A, B and C in Figure 4-4) produced by axial compression plus biaxial bending moments about the principal w- and z-axes using AISC *Specification* Equation H2-1. Points A and C are assumed at the angle mid-thickness at distances b and d (respectively) from the heel.

Note that for some sections, such as L3½×3×5/16, the calculated available strength can increase slightly as the unbraced length increases from zero, and then decrease as the unbraced length further increases.

Composite Compression—Member Selection Tables

Table 4-13. Rectangular HSS Filled with 4-ksi Normal Weight Concrete in Axial Compression

Available strengths in axial compression are given for rectangular HSS with F_y = 46 ksi (ASTM A500 Grade B) filled with 4-ksi normal weight concrete. The tabulated values are given for the effective length with respect to the y-axis $(KL)_y$. However, the effective length with respect to the x-axis $(KL)_x$ must also be investigated. To determine the available strength in axial compression, the table should be entered at the larger of $(KL)_y$ and $(KL)_{y\,eq}$, where

$$(KL)_{y\,eq} = \frac{(KL)_x}{\dfrac{r_{mx}}{r_{my}}} \tag{4-5}$$

Values of the ratio r_{mx}/r_{my} and other properties useful in the design of composite HSS compression members are listed at the bottom of Table 4-13. The variables r_{mx} and r_{my} are the radii of gyration for the composite cross section. The ratio r_{mx}/r_{my} is determined as

$$\frac{r_{mx}}{r_{my}} = \sqrt{\frac{P_{ex}(K_x L_x)^2}{P_{ey}(K_y L_y)^2}} \tag{4-6}$$

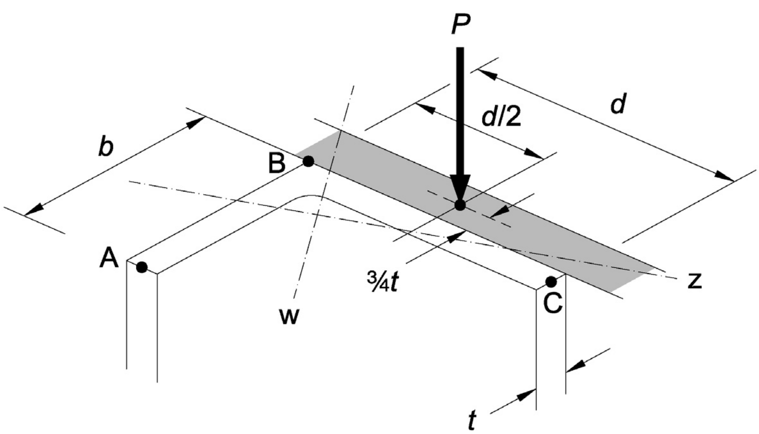

Fig. 4-4. Eccentrically loaded single angle.

For compact composite sections, the values of ϕM_n and M_n/Ω were calculated using the nominal moment strength equations for point B of the interaction diagram in Table C of the *Discussion of Limit State Response of Composite Columns and Beam-Columns Part II: Application of Design Provisions for the 2005 AISC Specification* (Geschwindner, 2010). For noncompact sections, the values of ϕM_n and M_n/Ω were calculated using the closed formed equations presented in the Commentary Figure C-I3-7.

The available strengths tabulated in Tables 4-13 through 4-20 are given for the indicated shape with the associated concrete fill. AISC *Specification* Section I2.2b stipulates that the available compressive strength of a filled composite member need not be less than that specified for a bare steel member. In these tables, available strengths controlled by the bare steel acting alone are identified. Additionally, there is no longitudinal reinforcement provided, because there is no requirement for minimum reinforcement in the AISC *Specification*. The use of filled shapes without longitudinal reinforcement is a common industry practice.

Table 4-14. Square HSS Filled with 4-ksi Normal Weight Concrete in Axial Compression

Table 4-14 is the same as Table 4-13, except that it provides available strengths in axial compression for square HSS filled with 4-ksi normal weight concrete.

Table 4-15. Rectangular HSS Filled with 5-ksi Normal Weight Concrete in Axial Compression

Table 4-15 is the same as Table 4-13, except that it provides available strengths in axial compression for rectangular HSS filled with 5-ksi normal weight concrete.

Table 4-16. Square HSS Filled with 5-ksi Normal Weight Concrete in Axial Compression

Table 4-16 is the same as Table 4-13, except that it provides available strengths in axial compression for square HSS filled with 5-ksi normal weight concrete.

Table 4-17. Round HSS Filled with 4-ksi Normal Weight Concrete in Axial Compression

Available strengths in axial compression are given for round HSS with F_y = 42 ksi (ASTM A500 Grade B) filled with 4-ksi normal weight concrete. To determine the available strength in axial compression, the table should be entered at the largest effective length, *KL*. Other properties useful in the design of compression members are listed at the bottom of Table 4-5.

The values of ϕM_n and M_n/Ω were calculated using the nominal moment strength equations for point B of the interaction diagram in Table D of the *Discussion of Limit State Response of Composite Columns and Beam-Columns Part II: Application of Design Provisions for the 2005 AISC Specification* (Geschwindner, 2010).

Table 4-18. Round HSS Filled with 5-ksi Normal Weight Concrete in Axial Compression

Table 4-18 is the same as Table 4-17, except that it provides available strengths in axial compression for round HSS filled with 5-ksi normal weight concrete.

Table 4-19. Pipe Filled with 4-ksi Normal Weight Concrete in Axial Compression

Available strengths in axial compression are given for pipe with F_y = 35 ksi (ASTM A53 Grade B) filled with 4-ksi normal weight concrete. To determine the available strength in axial compression, the table should be entered at the largest effective length, *KL*. Other properties useful in the design of compression members are listed at the bottom of Table 4-6.

Table 4-20. Pipe Filled with 5-ksi Normal Weight Concrete in Axial Compression

Table 4-20 is the same as Table 4-19, except that it provides available strengths in axial compression for pipe filled with 5-ksi normal weight concrete.

Table 4-21. Stiffness Reduction Factor τ_b

When an analysis is performed using the effective length method in AISC *Specification* Appendix Section 7.2, that procedure requires determination of the effective length factor, *K*. A common method of determining *K* is through the use of alignment charts provided in the AISC *Specification* Commentary.

When column buckling occurs in the inelastic range, the alignment charts usually give conservative results. For more accurate solutions, inelastic *K*-factors can be determined from the alignment chart by using τ_b times the elastic modulus of the columns in the equation for *G*. The stiffness reduction factor, τ_b, is the ratio of the tangent modulus, E_T , to the elastic modulus, *E*. Values are tabulated for steels with F_y = 35 ksi, 36 ksi, 42 ksi, 46 ksi and 50 ksi.

Table 4-22. Available Critical Stress for Compression Members

Table 4-22 provides the available critical stress for various ratios of *Kl/r*, for materials with a minimum specified yield strength of 35 ksi, 36 ksi, 42 ksi, 46 ksi and 50 ksi.

[c] Shape is noncompact for compression with $F_y = 46$ ksi. [f] Shape is noncompact for flexure with $F_y = 46$ ksi.
Note: Heavy line indicates KL/r_{my} equal to or greater than 200.
Dashed line indicates the KL beyond which bare steel strength controls.

F_y = 46 ksi
f'_c = 4 ksi

PART 5

DESIGN OF TENSION MEMBERS

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of members subject to static axial tension. For fatigue applications, see AISC *Specification* Appendix 3. For the design of members subject to eccentric tension or combined tension and flexure, see Part 6.

GROSS AREA, NET AREA AND EFFECTIVE NET AREA

In the determination of the available strength of a tension member, the gross area, A_g, is needed for the tensile yielding limit state and the effective net area, A_e, is needed for the tensile rupture limit state, as stipulated in AISC *Specification* Section D2.

Gross Area

The gross area, A_g, is determined as specified in AISC *Specification* Section B4.3a.

Effective Net Area

The effective net area, A_e, is determined from AISC *Specification* Section D3 by multiplying the net area, A_n, by the shear lag coefficient, U, where A_n is determined for tension members per AISC *Specification* Section B4.3b and U is determined from AISC *Specification* Table D3.1. Shear lag parameters are illustrated in AISC *Specification* Commentary Figures C-D3.1, C-D3.2 and C-D3.4.

TENSILE STRENGTH

The limit-state of tensile yielding will control the available tensile strength over tensile rupture when the following relationship is satisfied:

LRFD	ASD
$0.90F_yA_g \leq 0.75F_uA_e$ (5-1a)	$\dfrac{F_yA_g}{1.67} \leq \dfrac{F_uA_e}{2.00}$ (5-1b)

These expressions are both reduced to:

$$\frac{A_e}{A_g} \geq 1.2\frac{F_y}{F_u} \tag{5-2}$$

Otherwise, the limit state of tensile rupture will control over tensile yielding.

Yielding Limit State

The available tensile strength due to tensile yielding, which must equal or exceed the required strength, P_u or P_a, is determined for tension members, per AISC *Specification* Section D2(a), using Equation D2-1.

Rupture Limit State

The available tensile strength due to tensile rupture, which must equal or exceed the required strength, P_u or P_a, is determined for tension members, per AISC *Specification* Section D2(b) using Equation D2-2.

OTHER SPECIFICATION REQUIREMENTS AND DESIGN CONSIDERATIONS

Special Requirements for Heavy Shapes and Plates

For tension members with complete-joint-penetration groove welded joints and made from heavy shapes with a flange thickness exceeding 2 in. or built-up sections consisting of plates with a thickness exceeding 2 in., see AISC *Specification* Sections A3.1c and Section A3.1d.

Slenderness

Tension member slenderness ratio, L/r, should preferably be limited to a maximum of 300 per the User Note in AISC *Specification* Section D1. The intent of this recommendation is explained in the corresponding Commentary.

DESIGN TABLE DISCUSSION

Available tensile strengths for various types of tension members (see individual descriptions below) are given in Tables 5-1 through 5-8 for the limit states of tensile yielding and tensile rupture. In each case, the tabulated values for available tensile rupture strength are based upon the assumption that $A_e = 0.75A_g$, which is arbitrarily selected as a value that is practical to achieve with typical end connections. Such consideration of the effective net area during the design of the member will simplify the design of its end connections, which can be difficult to configure and costly if tension members are selected based upon available tensile yielding strength only, without considering the reduction in strength due to the connection.

When $A_e > 0.75A_g$, either the tabulated values for available tensile rupture strength can be used conservatively or the available tensile rupture strength can be calculated based upon the actual value of A_e. When $A_e < 0.75A_g$, the tabulated values of the available tensile rupture strength cannot be used, but rather must be calculated based upon the actual value of A_e.

Table 5-1. W-Shapes

Available strengths in axial tension are given for W-shapes with $F_y = 50$ ksi and $F_u = 65$ ksi (ASTM A992). Note that tensile rupture will control over tensile yielding for W-shapes with $F_y = 50$ ksi and $F_u = 65$ ksi when $A_e/A_g < 0.923$. Otherwise, tensile yielding will control over tensile rupture.

Table 5-2. Angles

Available strengths in axial tension are given for single angles with F_y = 36 ksi and F_u = 58 ksi (ASTM A36). Note that tensile rupture will control over tensile yielding for single angles with F_y = 36 ksi and F_u = 58 ksi when $A_e/A_g < 0.745$. Otherwise, tensile yielding will control over tensile rupture.

Table 5-3. WT-Shapes

Table 5-3 is similar to Table 5-1, except that it covers WT-shapes with F_y = 50 ksi and F_u = 65 ksi (ASTM A992).

Table 5-4. Rectangular HSS

Available strengths in axial tension are given for rectangular HSS with F_y = 46 ksi and F_u = 58 ksi (ASTM A500 Grade B). Note that tensile rupture will control over tensile yielding for rectangular HSS with F_y = 46 ksi and F_u = 58 ksi when $A_e/A_g < 0.952$. Otherwise, tensile yielding will control over tensile rupture.

Table 5-5. Square HSS

Table 5-5 is similar to Table 5-4, except that it covers square HSS with F_y = 46 ksi and F_u = 58 ksi (ASTM A500 Grade B).

Table 5-6. Round HSS

Available strengths in axial tension are given for ASTM A500 round HSS with F_y = 42 ksi and F_u = 58 ksi (ASTM A500 Grade B). Note that tensile rupture will control over tensile yielding for round HSS with F_y = 42 ksi and F_u = 58 ksi when $A_e/A_g < 0.869$. Otherwise, tensile yielding will control over tensile rupture.

Table 5-7. Pipe

Available strengths in axial tension are given for pipe with F_y = 35 ksi and F_u = 60 ksi (ASTM A53 Grade B). Note that tensile rupture will control over tensile yielding for pipe with F_y = 35 ksi and F_u = 60 ksi when $A_e/A_g < 0.700$. Otherwise, tensile yielding will control over tensile rupture.

Table 5-8. Double Angles

Available strengths in axial tension are given for double angles with F_y = 36 ksi and F_u = 58 ksi (ASTM A36). Note that tensile rupture will control over tensile yielding for double angles with F_y = 36 ksi and F_u = 58 ksi when $A_e/A_g < 0.745$. Otherwise, tensile yielding will control over tensile rupture.

F_y = 50 ksi
F_u = 65 ksi

Limit State	ASD	LRFD
Yielding	$\Omega_t = 1.67$	$\phi_t = 0.90$
Rupture	$\Omega_t = 2.00$	$\phi_t = 0.75$

[h] Flange thickness is greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.

Note: Tensile rupture on the effective net area will control over tensile yielding on the gross area unless the tension member is selected so that an end connection can be configured with $A_e \geq 0.923A_g$.

Yielding	$\Omega_t = 1.67$	$\phi_t = 0.90$
Rupture	$\Omega_t = 2.00$	$\phi_t = 0.75$

Note: Tensile rupture on the effective net area will control over tensile yielding on the gross area unless the tension member is selected so that an end connection can be configured with $A_e \geq 0.745A_g$.

×3/16	1.44	1.08	31.0	46.7	31.3	47.0
×1/8	0.982	0.737	21.2	31.8	21.4	32.1

Limit State	ASD	LRFD
Yielding	$\Omega_t = 1.67$	$\phi_t = 0.90$
Rupture	$\Omega_t = 2.00$	$\phi_t = 0.75$

Note: Tensile rupture on the effective net area will control over tensile yielding on the gross area unless the tension member is selected so that an end connection can be configured with $A_e \geq 0.745A_g$.

PART 6

DESIGN OF MEMBERS SUBJECT TO COMBINED FORCES

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of members subject to combined forces. For the design of members subject to axial tension only, see Part 5. For the design of members subject to axial compression only, see Part 4. For the design of members subject to uniaxial flexure only, see Part 3.

COMPACT, NONCOMPACT AND SLENDER-ELEMENT SECTIONS

Based upon the types of load transmitted by the member, the discussions of width-to-thickness ratios in Part 4 for compression members and Part 3 for flexural members apply to the design of members subject to combined forces. The values given in this Part already account for limitations due to width-to-thickness ratios.

MEMBERS SUBJECT TO COMBINED FLEXURE AND AXIAL COMPRESSION

The interaction of the combined effects of the required strengths (axial compression and bending moment) must satisfy the unity check as follows:

1. For doubly and singly symmetric members, per AISC *Specification* Section H1.1
2 For unsymmetric and other members, per AISC *Specification* Section H2

MEMBERS SUBJECT TO COMBINED FLEXURE AND AXIAL TENSION

The interaction of the combined effects of the required strengths (axial tension and bending moment) must satisfy the unity check as follows:

1. For doubly and singly symmetric members, per AISC *Specification* Section H1.2
2. For unsymmetric and other members, per AISC *Specification* Section H2

MEMBERS SUBJECT TO TORSION AND COMBINED TORSION, FLEXURE, SHEAR AND/OR AXIAL FORCE

The interaction of the combined effects of the required strengths (torsion, bending moment, shear force and/or axial force) must satisfy the requirements of AISC *Specification* Section H3.

See also AISC Design Guide 9, *Torsional Analysis of Structural Steel Members*.

MEMBERS WITH HOLES

AISC *Specification* Section F13 provides provisions for potential impact of holes in shapes proportioned on the basis of flexural strength of the gross section. Additionally, AISC *Specification* Section H4 provides provisions applicable to rupture of flanges with holes subject to tension under combined axial force and major axis flexure.

COMPOSITE MEMBERS SUBJECT TO COMBINED FLEXURE AND AXIAL COMPRESSION

For the design of composite members subject to combined flexure and axial compression, see AISC *Specification* Section I5.

DESIGN TABLE DISCUSSION

Table 6-1. W-Shapes in Combined Flexure and Axial Force

Steel W-shapes with $F_y = 50$ ksi (ASTM A992) and subject to combined axial force (tension or compression) and flexure may be checked for compliance with the provisions of Section H1.1 and H1.2 of the AISC *Specification* using values listed in Table 6-1 and the appropriate interaction equations provided in the following sections.

Values p, b_x, b_y, t_y and t_r presented in Table 6-1 are defined as follows.

	LRFD	ASD
Axial Compression	$p = \dfrac{1}{\phi_c P_n}$, (kips)$^{-1}$	$p = \dfrac{\Omega_c}{P_n}$, (kips)$^{-1}$
Strong Axis Bending	$b_x = \dfrac{8}{9\phi_b M_{nx}}$, (kip-ft)$^{-1}$	$b_x = \dfrac{8\Omega_b}{9M_{nx}}$, (kip-ft)$^{-1}$
Weak Axis Bending	$b_y = \dfrac{8}{9\phi_b M_{ny}}$, (kip-ft)$^{-1}$	$b_y = \dfrac{8\Omega_b}{9M_{ny}}$, (kip-ft)$^{-1}$
Tension Yielding	$t_y = \dfrac{1}{\phi_t F_y A_g}$, (kips)$^{-1}$	$t_y = \dfrac{\Omega_t}{F_y A_g}$, (kips)$^{-1}$
Tension Rupture	$t_r = \dfrac{1}{\phi_t F_u (0.75A_g)}$, (kips)$^{-1}$	$t_r = \dfrac{\Omega_t}{F_u (0.75A_g)}$, (kips)$^{-1}$

Combined Flexure and Compression

Equations H1-1a and H1-1b of the AISC *Specification* may be written as follows using the coefficients listed in Table 6-1 and defined above.

When $pP_r \geq 0.2$:

$$pP_r + b_x M_{rx} + b_y M_{ry} \leq 1.0 \tag{6-1}$$

When $pP_r < 0.2$:

$$\tfrac{1}{2} pP_r + \tfrac{9}{8}\left(b_x M_{rx} + b_y M_{ry}\right) \leq 1.0 \tag{6-2}$$

The designer may check acceptability of a given shape using the appropriate interaction equation from above. See Aminmansour (2000) for more information on this method, including an alternative approach for selection of a trial shape.

Combined Flexure and Tension

Equations H1-1a and H1-1b of the AISC *Specification* may be written as follows using the coefficients listed in Table 6-1 and defined above.

When $pP_r \geq 0.2$:

$$(t_y \text{ or } t_r)\, P_r + b_x M_{rx} + b_y M_{ry} \leq 1.0 \quad (6\text{-}3)$$

When $pP_r < 0.2$:

$$\tfrac{1}{2}(t_y \text{ or } t_r)\, P_r + \tfrac{9}{8}(b_x M_{rx} + b_y M_{ry}) \leq 1.0 \quad (6\text{-}4)$$

The larger value of t_y and t_r should be used in the above equations.

The designer may check acceptability of a given shape using the appropriate interaction equation from above along with variables t_r, t_y, b_x and b_y. See Aminmansour (2006) for more information on this method.

It is noted that the values for t_r listed in Table 6-1 are based on the assumption that $A_e = 0.75A_g$. See Part 5 for more information on this assumption. When $A_e > 0.75A_g$, the tabulated values for t_r are conservative. When $A_e < 0.75A_g$, t_r must be calculated based upon the actual value of A_e.

General Considerations for Use of Values Listed in Table 6-1

The following remarks are offered for consideration in use of the values listed in Table 6-1.

1. Values of p, b_x and b_y already account for section compactness and can be used directly.
2. Tabulated values of b_x assume that $C_b = 1.0$. A procedure for determining b_x when $C_b > 1.0$ follows.
3. Given that the limit state of lateral-torsional buckling does not apply to W-shapes bent about their weak axis, values of b_y are independent of unbraced length and C_b.
4. Values of b_x equally apply to combined flexure and compression as well as combined flexure and tension.
5. Smaller values of variable p for a given KL and smaller values of b_x for a given L_b indicate higher strength for the type of load in question. For example, a section with a smaller p at a certain KL is more effective in carrying axial compression than another section with a larger value of p at the same KL. Similarly, a section with a smaller b_x is more effective for flexure at a given L_b than another section with a larger b_x for the same L_b. This information may be used to select more efficient shapes when relatively large amounts of axial load or bending are present.

Determination of b_x when $C_b > 1.0$

The tabulated values of b_x assume that $C_b = 1.0$. These values may be modified in accordance with AISC *Specification* Sections F1 and H1.2. The following procedure may be used to account for $C_b > 1.0$.

$$b_{x(C_b > 1.0)} = \frac{b_{x(C_b = 1.0)}}{C_b} \geq b_{xmin} \quad (6\text{-}5)$$

Values of b_{xmin} are listed in Table 6-1 at L_b = 0 ft. See Aminmansour (2009) for more information on this method. Values for p, b_x, b_y, t_y and t_r presented in Table 6-1 have been multiplied by 10^3. Thus, when used in the appropriate interaction equation they must be multiplied by 10^{-3} (0.001).

[c] Shape is slender for compression with $F_y = 50$ ksi.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi; therefore, $\phi_v = 0.90$ and $\Omega_v = 1.67$.
Note: Heavy line indicates KL/r_y equal to or greater than 200.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi; therefore, $\phi_v = 0.90$ and $\Omega_v = 1.67$.
Note: Heavy line indicates KL/r_y equal to or greater than 200.

F_y = 50 ksi

r_y, in.	2.10		2.09		3.65	

[c] Shape is slender for compression with $F_y = 50$ ksi.
[h] Flange thickness greater than 2 in. Special requirements may apply per AISC *Specification* Section A3.1c.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi; therefore, $\phi_v = 0.90$ and $\Omega_v = 1.67$.
Note: Heavy line indicates KL/r_y equal to or greater than 200.

F_y = 50 ksi

[c] Shape is slender for compression with F_y = 50 ksi.

[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with F_y = 50 ksi; therefore, ϕ_v = 0.90 and Ω_v = 1.67.

Note: Heavy line indicates KL/r_y equal to or greater than 200.

r_x/r_y	4.86				6.29				4.96			
r_y, in.	1.73				1.30				1.66			

[c] Shape is slender for compression with F_y = 50 ksi.

[f] Shape does not meet compact limit for flexure with F_y = 50 ksi.

Note: Heavy line indicates KL/r_y equal to or greater than 200.

F_y = 50 ksi

[c] Shape is slender for compression with $F_y = 50$ ksi.
[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi; therefore, $\phi_v = 0.90$ and $\Omega_v = 1.67$.
Note: Heavy line indicates KL/r_y equal to or greater than 200.

F_y = 50 ksi

[c] Shape is slender for compression with $F_y = 50$ ksi.

[v] Shape does not meet the h/t_w limit for shear in AISC *Specification* Section G2.1(a) with $F_y = 50$ ksi; therefore, $\phi_v = 0.90$ and $\Omega_v = 1.67$.

Note: Heavy line indicates KL/r_y equal to or greater than 200.

PART 7

DESIGN CONSIDERATIONS FOR BOLTS

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of bolts in steel-to-steel structural connections. Additional guidance on bolt design is available in AISC Design Guide 17, *High Strength Bolts—A Primer for Structural Engineers,* (Kulak, 2002). For the design of steel-to-concrete anchorage, see Part 14. For the design of connection elements, see Part 9. For the design of simple shear, moment, bracing and other connections, see Parts 10 through 15.

GENERAL REQUIREMENTS FOR BOLTED JOINTS

Fastener Components

The applicable material specifications for fastener components are as given in Part 2. For convenience in referencing and consistent with AISC *Specification* Section J3.1, ASTM A325 and F1852 bolts have been labelled Group A bolts, and ASTM A490 and F2280 bolts have been labelled Group B bolts.

Material and storage requirements for fastener components are as given in AISC *Specification* Section A3.3 and RCSC *Specification* Section 2. The compatibility of ASTM A563 nuts and F436 washers with ASTM A325, F1852, A490 and F2280 bolts is as given in RCSC *Specification* Table 2.1. These products are given identifying marks, as illustrated in RCSC *Specification* Figure C-2.1. Alternative-design fasteners and alternative washer-type indicating devices are permitted, subject to the requirements in RCSC *Specification* Sections 2.8 and 2.6.2, respectively.

Mixing grades of fasteners raises inventory and quality control issues associated with the use of multiple fastener grades. When both Group A and Group B bolts are used on a project, different diameters can be specified for each to help ensure that the Group B bolts are installed in the proper location.

Regardless of the bolt type selected, the typical sizes of $^3/_4$-in., $^7/_8$-in., 1-in. and $1^1/_8$-in. diameter are usually preferred. Diameters above 1 in. require special consideration for availability as well as installation, when pretensioned installation is required. Special equipment may be required to pretension large-diameter Group B bolts.

Proper Selection of Bolt Length

Per RCSC *Specification* Section 2.3.2, adequate thread engagement is developed when the end of the bolt is at least flush with or projects beyond the face of the nut. To provide for this, the ordered length of Group A and Group B bolts should be calculated as the grip (see Figure 7-1) plus the nominal thickness of washers and/or direct-tension indicators, if used, plus the allowance from Table 7-14, with the total rounded to the next higher increment of $^1/_4$ in. up to a 5-in. length and the next higher $^1/_2$ in. over a 5-in. length. Note that bolts longer than 5 in. are generally available only in $^1/_2$-in. increments, except by special arrangement with the manufacturer or vendor. While longer lengths may be ordered, an 8-in. length is generally the maximum stock length available. Requirements for a minimum stick-through greater than zero are discouraged because of the risk of jamming the nut on the thread runout, particularly in the bolt length range available only in $^1/_2$-in. increments. See Carter (1996) for further information.

Washer Requirements

Requirements for the use of ASTM F436 washers and/or plate washers are given in RCSC *Specification* Section 6.

Nut Requirements

The compatibility of ASTM A563 nuts with Group A and Group B bolts is as given in RCSC *Specification* Table 2.1.

Bolted Parts

The requirements for connected plies, faying surfaces, bolt holes and burrs are given in AISC *Specification* Sections J3.2 and M2.5, and RCSC *Specification* Section 3. Spacing and edge distance requirements are given in AISC *Specification* Sections J3.3, J3.4 and J3.5.

PROPER SPECIFICATION OF JOINT TYPE

When Group A or Group B high-strength bolts are to be used, the joint type must be specified as snug-tightened, pretensioned or slip-critical, per AISC *Specification* Section J3.1.

Snug-Tightened Joints

Snug-tightened joints simplify design, installation and inspection and should be specified whenever pretensioned joints and slip-critical joints are not required. The applicability is summarized and design requirements, installation requirements and inspection requirements are stipulated for snug-tightened joints per RCSC *Specification* Section 4.1. Faying surfaces in snug-tightened joints must meet the requirements in RCSC *Specification* Sections 3.2 and 3.2.1, but not those for slip-critical joints in RCSC *Specification* Section 3.2.2. Note that there is generally no need to limit the actual level of pretension provided in snug-tightened joints, per RCSC *Specification* Section 9.1.

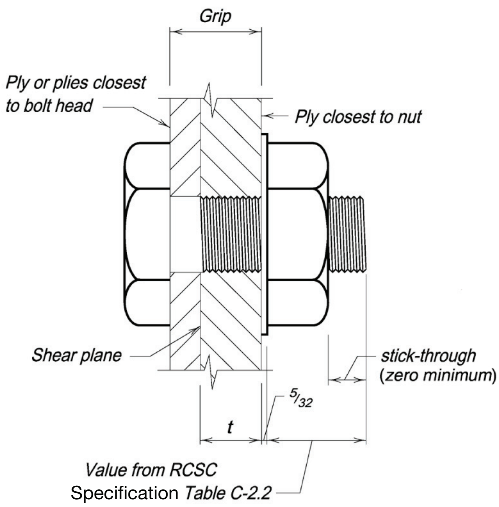

Fig. 7-1. Grip and other parameters for bolt length selection.

Pretensioned Joints

When pretension is required but slip-resistance is not of concern, a pretensioned joint should be specified. The applicability is summarized and design requirements, installation requirements and inspection requirements are stipulated for pretensioned joints per RCSC *Specification* Section 4.2. Additionally, pretensioned joints are required by default in some cases per AISC *Specification* Section J1.10. Faying surfaces in pretensioned joints must meet the requirements in RCSC *Specification* Sections 3.2 and 3.2.1, but not those for slip-critical joints in RCSC *Specification* Section 3.2.2.

Slip-Critical Joints

The applicability of slip critical joints is summarized and design requirements, installation requirements, and inspection requirements are stipulated in RCSC *Specification* Section 4.3, except as modified by AISC *Specification* Sections J3.8 and J3.9. Faying surfaces in slip-critical joints must meet the requirements in RCSC *Specification* Sections 3.2 and 3.2.2. RCSC defines a faying surface as “the plane of contact between two plies of a joint.” Note that the surfaces under the bolt head, washer and/or nut are not faying surfaces.

Subject to the requirements in RCSC *Specification* Section 4.3, slip-critical joints are rarely required in building design. Slip-critical joints are appreciably more expensive because of the associated costs of faying surface preparation and installation and inspection requirements.

When slip-resistance is required and the steel is painted, the fabricator should be consulted to determine the most economical approach to providing the necessary slip resistance. Special paint systems that are rated for slip resistance can be specified. Alternatively, a paint system that is not rated for slip resistance can be used with the faying surfaces masked.

DESIGN REQUIREMENTS

Design requirements are found in the AISC *Specification* as follows. In each case, the available strength determined in accordance with these provisions must equal or exceed the required strength. These requirements are derived from those in the RCSC *Specification*.

Shear

Available shear strength is determined as given in RCSC *Specification* Section 5.1 and AISC *Specification* Section J3.6, with consideration of the presence of fillers or shims, per RCSC *Specification* Section 5.1 and AISC *Specification* Section J5. The nominal shear strengths given in Table J3.2 have been reduced by approximately 10% from statistical results of tests to account for uneven force distributions associated with end loading and other effects normally neglected in the design process.

When the length of a bolted joint measured parallel to the line of force exceeds 38 in., a 16.7% strength reduction may be applicable, per AISC *Specification* Table J3.2 footnote a.

The force that can be resisted by a snug-tightened or pretensioned high-strength bolt may also be limited by the bearing strength at the bolt hole per AISC *Specification* Section J3.10. The effective strength of an individual bolt may be taken as the lesser of the shear strength per Section J3.6 or the bearing strength at the bolt hole per Section J3.10. The strength of the bolt group may be taken as the sum of the effective strengths of the individual fasteners.

Tension

Available tensile strength is determined as given in RCSC *Specification* Section 5.1 and AISC *Specification* Section J3.6, with consideration of the effects of prying action, if any. Prying action is a phenomenon (in bolted construction only) whereby the deformation of a fitting under a tensile force increases the tensile force in the bolt. While the effect of prying action is relevant to the design of the bolts, it is primarily a function of the strength and stiffness of the connection elements. Prying action is addressed in Part 9.

Combined Shear and Tension

Available strength for combined shear and tension in bearing-type connections is determined as given in RCSC *Specification* Section 5.2 and AISC *Specification* Section J3.7.

Bearing Strength at Bolt Holes

Available bearing strength at bolt holes is determined as given in RCSC *Specification* Section 5.3 and AISC *Specification* Section J3.10.

Slip Resistance

The available strength of slip-critical connections is determined in accordance with AISC *Specification* Section J3.8. The available strength, ϕR_n or R_n/Ω, is determined by applying the resistance factor or safety factor appropriate for the hole type used.

ECCENTRICALLY LOADED BOLT GROUPS

Eccentricity in the Plane of the Faying Surface

When eccentricity occurs in the plane of the faying surface, the bolts must be designed to resist the combined effect of the direct shear, P_u or P_a, and the additional shear from the induced moment, $P_u e$ or $P_a e$. Two analysis methods for this type of eccentricity are the instantaneous center of rotation method and the elastic method.

The instantaneous center of rotation method is more accurate, but generally requires the use of tabulated values or an iterative solution. The elastic method is simplified, but may be excessively conservative because it neglects the ductility of the bolt group and the potential for load redistribution.

Instantaneous Center of Rotation Method

Eccentricity produces both a rotation and a translation of one connection element with respect to the other. The combined effect of this rotation and translation is equivalent to a rotation about a point defined as the instantaneous center of rotation (IC), as illustrated in Figure 7-2(a). The location of the IC depends upon the geometry of the bolt group as well as the direction and point of application of the load.

The load-deformation relationship for one bolt is illustrated in Figure 7-3, where

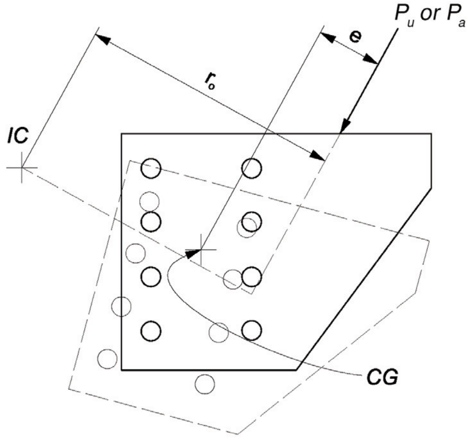
$$R = R_{ult}(1 - e^{-10\Delta})^{0.55} \qquad (7\text{-}1)$$

where

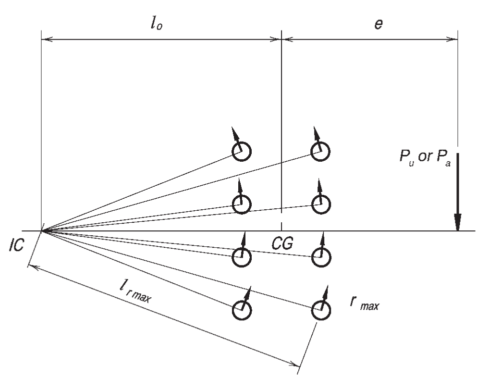
R = nominal shear strength of one bolt at a deformation Δ, kips
R_{ult} = ultimate shear strength of one bolt, kips
Δ = total deformation, including shear, bearing and bending deformation in the bolt and bearing deformation of the connection elements, in.
e = 2.718…, base of the natural logarithm

The nominal shear strength of the bolt most remote from the IC can be determined by applying a maximum deformation, Δ_{max}, to that bolt. The load-deformation relationship is based upon data obtained experimentally for $^3/_4$-in.-diameter ASTM A325 bolts, where R_{ult} = 74 kips, and Δ_{max} = 0.34 in.

The nominal shear strengths of the other bolts in the joint can be determined by applying a deformation Δ that varies linearly with distance from the IC. The nominal shear strength of the bolt group is, then, the sum of the individual strengths of all bolts.



(a) Instantaneous center of rotation (IC)



(b) Forces on bolts in group for case of θ = 0° for simplicity

Fig. 7-2. Illustration for instantaneous center of rotation method.

The individual resistance of each bolt is assumed to act on a line perpendicular to a ray passing through the IC and the centroid of that bolt, as illustrated in Figure 7-2(b). If the correct location of the IC has been selected, the three equations of in-plane static equilibrium ($\Sigma F_x = 0$, $\Sigma F_y = 0$, and $\Sigma M = 0$) will be satisfied.

For further information, see Crawford and Kulak (1968).

Elastic Method

For a force applied as illustrated in Figure 7-4, the eccentric force, P_u or P_a, is resolved into a direct shear, P_u or P_a, acting through the center of gravity (CG) of the bolt group and a moment, $P_u e$ or $P_a e$, where e is the eccentricity. Each bolt is then assumed to resist an equal share of the direct shear and a share of the eccentric moment proportional to its distance from the CG. The resultant vectorial sum of these forces is the required strength for the bolt, r_u or r_a.

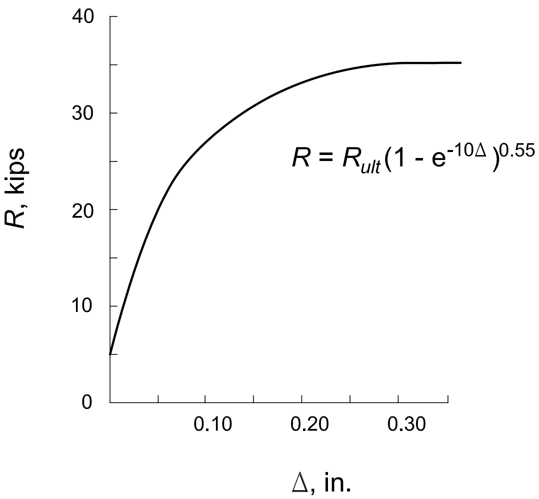


Fig. 7-3. Load-deformation relationship for one 3/4-in.-diameter ASTM A325 bolt in single shear.

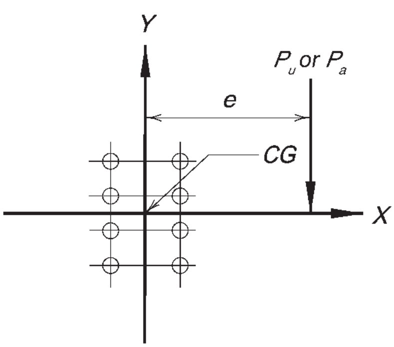

Fig. 7-4. Illustration for elastic method.

The shear per bolt due to the concentric force, P_u or P_a, is r_{pu} or r_{pa}, where

LRFD	ASD
$r_{pu} = \dfrac{P_u}{n}$ (7-2a)	$r_{pa} = \dfrac{P_a}{n}$ (7-2b)

and n is the number of bolts. To determine the resultant forces on each bolt when P_u or P_a is applied at an angle θ with respect to the vertical, r_{pu} or r_{pa} must be resolved into horizontal component, r_{pxu} or r_{pxa}, and vertical component, r_{pyu} or r_{pya}, where

$$r_{pxu} = r_{pu}\sin\theta \text{ (LRFD)} \tag{7-3a}$$
$$r_{pxa} = r_{pa}\sin\theta \text{ (ASD)} \tag{7-3b}$$
$$r_{pyu} = r_{pu}\cos\theta \text{ (LRFD)} \tag{7-4a}$$
$$r_{pya} = r_{pa}\cos\theta \text{ (ASD)} \tag{7-4b}$$

The shear on the bolt most remote from the CG due to the moment, P_ue or P_ae, is r_{mu} or r_{ma}, where

LRFD	ASD
$r_{mu} = \dfrac{P_u ec}{I_p}$ (7-5a)	$r_{ma} = \dfrac{P_a ec}{I_p}$ (7-5b)

where

c = radial distance from CG to center of bolt most remote from CG, in.

$I_p = I_x + I_y$ = polar moment of inertia of the bolt group, in.^{4} per in.^{2}

To determine the resultant force on the most highly stressed bolt, r_{mu} or r_{ma} must be resolved into horizontal component r_{mxu} or r_{mxa} and vertical component r_{myu} or r_{mya}, where

LRFD	ASD
$r_{mxu} = \dfrac{P_u ec_y}{I_p}$ (7-6a)	$r_{mxa} = \dfrac{P_a ec_y}{I_p}$ (7-6b)
$r_{myu} = \dfrac{P_u ec_x}{I_p}$ (7-7a)	$r_{mya} = \dfrac{P_a ec_x}{I_p}$ (7-7b)

In the above equations, c_x and c_y are the horizontal and vertical components of the diagonal distance c. Thus, the required strength per bolt is r_u or r_a, where

LRFD	ASD
$r_u = \sqrt{\left(r_{pxu} + r_{mxu}\right)^2 + \left(r_{pyu} + r_{myu}\right)^2}$ (7-8a)	$r_a = \sqrt{\left(r_{pxa} + r_{mxa}\right)^2 + \left(r_{pya} + r_{mya}\right)^2}$ (7-8b)

For further information, see Higgins (1971).

Eccentricity Normal to the Plane of the Faying Surface

Eccentricity normal to the plane of the faying surface produces tension above and compression below the neutral axis for a bracket connection as shown in Figure 7-5. The eccentric force, P_u or P_a, is resolved into a direct shear, P_u or P_a, acting at the faying surface of the joint and a moment normal to the plane of the faying surface, $P_u e$ or $P_a e$, where e is the eccentricity. Each bolt is then assumed to resist an equal share of the concentric force, P_u or P_a, and the moment is resisted by tension in the bolts above the neutral axis and compression below the neutral axis.

Two design approaches for this type of eccentricity are available: Case I, in which the neutral axis is not taken at the center of gravity (CG), and Case II, in which the neutral axis is taken at the CG.

Case I—Neutral Axis Not at Center of Gravity

The shear per bolt due to the concentric force, r_{uv} or r_{av}, is determined as

LRFD	ASD
$r_{uv} = \dfrac{P_u}{n}$ (7-9a)	$r_{av} = \dfrac{P_a}{n}$ (7-9b)

where n is the number of bolts in the connection.

A trial position for the neutral axis can be selected at one-sixth of the total bracket depth, measured upward from the bottom (line X-X in Figure 7-6(a)). To provide for reasonable proportions and to account for the bending stiffness of the connection elements, the effective width of the compression block, b_{eff}, should be taken as

$$b_{eff} = 8t_f \le b_f \qquad (7\text{-}10)$$

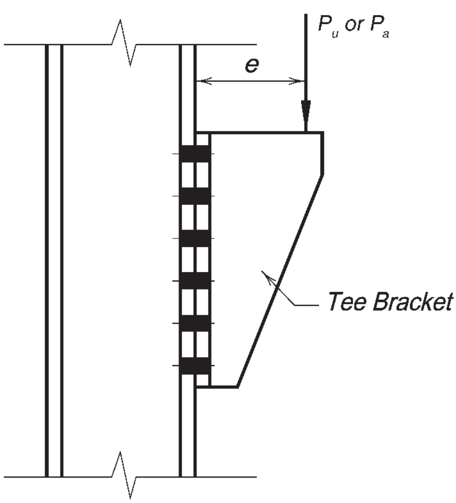

Fig. 7-5. Tee bracket subject to eccentric loading normal to the plane of the faying surface.

where

t_f = lesser connection element thickness, in.
b_f = connection element width, in.

This effective width is valid for bracket flanges made from W-shapes, S-shapes, welded plates and angles. Where the bracket flange thickness is not constant, the average flange thickness should be used.

The assumed location of the neutral axis can be evaluated by checking static equilibrium assuming an elastic stress distribution. Equating the moment of the bolt area above the neutral axis with the moment of the compression block area below the neutral axis,

$$(\Sigma A_b)y = b_{eff}d\,(d/2) \tag{7-11}$$

where

ΣA_b = sum of the areas of all bolts above the neutral axis, in.^{2}
y = distance from line X-X to the CG of the bolt group above the neutral axis, in.
d = depth of compression block, in.

The value of d may then be adjusted until a reasonable equality exists.
